Asymmetric rheumatoid vasculitis in a hemiplegic patient

In 1962, Thomson and Bywaters described the phenomenon of unilateral rheumatoid arthritis occurring in a hemiplegic patient.1 Oblick subsequently described a similar sparing in a patient in whom the limbs had been paralysed as a result of poliomyelitis.2 This protection was initially explained by lack of use of the hemiplegic limb, sparing the joints. More recently, a neurogenic mechanism has been proposed.3

The case to be described is of rheumatoid vasculitis which largely spared the hemiplegic side—a phenomenon not described previously. It is suggested that the asymmetric distribution supports a neurogenic mechanism.

The patient, who suffered from an arteriopathy, had his first myocardial infarction at the age of 37. A second infarct one year later was followed rapidly by a cerebrovascular accident, thought to arise from embolism of a left ventricular wall thrombus, seen on the echocardiogram. This resulted in a dense left hemiplegia. In 1988, at the age of 48, he developed seropositive rheumatoid arthritis and presented with a predominance of right-sided synovitis, involving the right hand, knee and ankle, although there was mild involvement of the left hemiplegic side. He was treated with Voltarol retard, sulphasalazine 1 g twice daily and chloroquine 250 mg three times a week, which produced good disease control and a decrease in the erythrocyte sedimentation rate from 50 to 25 mm/1st h. Radiographs of the hands, taken two years later, showed bilateral erosions; joint space loss was considerably greater on the right side.

In April 1994, at the age of 51, the patient presented with a predominantly right sided vasculitic rash involving his hand, arm, foot, thigh, and buttock, with vasculitic ulcers on his right thigh and buttock (figure). He had nail fold infarcts of the right fingers and toes. Peripheral pulses were present and equal; joints were not active. There was no evidence of peripheral neuropathy, and no fever. There had been no recent change in medication to suggest a drug induced aetiology. Urine analysis was negative. Immunological studies showed him to be negative to antinuclear factor, antineutrophil cytoplasmic antibodies, and lupus anticoagulant, but positive to La(SS-B) antibody. A skin biopsy demonstrated a leucocytoclastic vasculitis. He was treated with intermittent pulses intravenous cyclophosphamide 15 mg/kg and prednisolone. The rash faded and healed over the first two weeks of treatment, and he made a good subsequent recovery.

Whilst one could explain the unilateral rheumatoid joint involvement, a hemiplegic patient in terms of joint sparing in the paralysed limb, this mechanism could not be evoked to explain the predominantly unilateral distribution of the vasculitis to the non-hemiplegic side as described in this patient. This may provide further support for a neurogenic mechanism.

Evidence for sensory nerve involvement in chronic arthritis comes from animal studies in which sectioning of the sciatic nerve seven days before the induction of adjuvant arthritis delayed the onset and severity of disease in the operated limb.4 Levine has suggested that neuromechanisms may also explain why rheumatoid arthritis is bilaterally symmetric.5 Evidence is growing that these effects are mediated through substance P in the sympathetic nervous system.6

The vasculitis in rheumatoid arthritis is predominantly small vessel and is caused by a precipitate of immune complex with subsequent polymorphonuclear leukocyte infiltration.7 Why the vasculitis should have occurred asymmetrically in this patient is unknown. There was no recent change in his medication to suggest a drug induced aetiology. The cerebrovascular accident predated the vasculitis by 10 years and was embolic; it was thus unlikely to have been the result of a single vascular process such as Sneddon’s syndrome. One could speculate that alteration in vasomotor sympathetic tone in the hemiplegic limb8 9 could decrease the local precipitation of immune complexes and thus explain the unilateral rheumatoid vasculitis described here.
