Abstract

Objective—To investigate the association of complement C4 allotypes with rheumatoid arthritis in Koreans.

Methods—65 rheumatoid arthritis patients and 255 controls were typed for C4 allotypes and HLA-A, B, C, DR, and DQ antigens.

Results—The frequencies of C4AQ0 (32.3% v 14.9%, P < 0.005) and C4B5 (29.2% v 12.2%, P < 0.005) were significantly increased in rheumatoid arthritis patients compared with healthy control subjects. Among rheumatoid patients, the frequency of C4AQ0 was significantly increased in both the rheumatoid factor (RF) positive (27.3%) and the RF negative (66.7%) subgroups. The frequencies of C4B5 and HLA-DR4 were significantly increased only in RF positive subgroup. C4B5 was strongly associated with HLA-DR4, whereas C4AQ0 did not show association with DR4.

Conclusions—In Koreans, C4AQ0 and C4B5 are associated with susceptibility to rheumatoid arthritis, as in the Japanese. C4B5 is strongly associated with HLA-DR4. C4AQ0 is considered to be a DR4 independent risk factor, and a disease susceptibility allele in linkage disequilibrium with C4AQ0 is suggested in Korean patients with rheumatoid arthritis.

The association of rheumatoid arthritis with HLA-DR4 is well established, and confirmed in many ethnic groups.1 It remains unclear, however, whether DR4 itself, or a susceptibility gene closely linked to DR4, is important for the occurrence of rheumatoid arthritis. In this context, there has been interest in the class III region of the major histocompatibility complex (MHC), which contains the genes coding for the second component of complement (C2), factor B (BF), and the fourth component of complement (C4A and C4B). However, reports on the association between rheumatoid arthritis and allotypes of BF, C4A, and C4B have been controversial.2,3

Recently the association of complement alleles C4AQ0 and C4B5 with rheumatoid arthritis has been reported in the Japanese.9 This finding has not been confirmed in other ethnic groups. The genetic background of Koreans is most close to that of the Japanese among east Asian ethnic groups from the point of view of HLA genes and haplotypes.12 Therefore, we decided to investigate the association of C4 allotypes with rheumatoid arthritis in Korean patients to gain a better understanding of the immunogenetics of the disease. For the study of HLA class I and II allelic associations with rheumatoid arthritis in Koreans, HLA-A, B, C, DR, and DQ antigens were also examined in rheumatoid patients and controls.

Methods

PATIENTS

Blood specimens were obtained from 65 randomly selected Korean patients with rheumatoid arthritis, diagnosed according to the American Rheumatism Association criteria.13 There were 10 men and 55 women. Mean age at the time of the study was 47 (range 19 to 68) and mean disease duration was 8.4 years (range 1 to 30 years). Rheumatoid factor (RF) was positive in 55 patients, using the latex test. Rheumatoid nodules were present in four patients, and extra-articular signs other than rheumatoid nodules in six patients, including one case of Felty syndrome. Clinical stages were II in 30 patients, III in 30 patients, and IV in one patient. Controls were 255 healthy Koreans, including 156 parents from family study material for the analysis of extended HLA haplotypes.

C4 TYING

EDTA treated plasma samples were used for C4 typing and the procedure was essentially the same as previously described.6 In brief, EDTA-plasma samples pretreated with carboxypeptidase B and neuraminidase were typed for C4A and C4B allotypes using high voltage agarose gel electrophoresis followed by immunofixation. C4B bands were further detected by a C4 dependent haemolytic overlay method. The nomenclature (1990) used for the C4 allotypes was according to Mauff et al.14

HLA TYING

Typing for HLA-A, B, C, DR, and DQ antigens was carried out by standard microcytotoxicity test using T and B lymphocytes separated by nylon wool column.

STATISTICAL ANALYSIS

The χ² test or Fisher exact test was used to compare findings for rheumatoid arthritis patients with those for control subjects. Odds ratios and 95% confidence limits were calculated using the PC SAS program.

* Percent shown in parentheses. † C4A4Q0 and C4BQO are all probable heterozygous allotypes except homozygous C4AQ0 in one control and one RA patient, and homozygous C4BQ0 in two RA patients. C4AR and C4BR are rare alleles. ‡ NS, not significant.

Results

Frequencies of C4 allotypes

Table 1 shows the distribution of C4A and C4B allotypes in the controls and rheumatoid arthritis patients. For C4A allotypes, the frequency of C4AQ0 was increased in rheumatoid arthritis patients compared with controls (32.3% vs 14.9%, P < 0.005, odds ratio [OR] 2.7). For C4B allotypes, the frequency of C4B5 was increased in rheumatoid arthritis patients compared with controls (29.2% vs 12.6%, P < 0.005, OR 2.9), while that of C4B1 was decreased (75.4% vs 88.6%, P < 0.05, OR 0.4). The frequency of having both C4AQ0 and C4B5 allotypes was increased in rheumatoid patients (6.2% vs 0.4%, P < 0.01, OR 16.7).

The relations between presence of rheumatoid factor (RF) and complement C4A and C4B allotypes were also found in rheumatoid arthritis patients, whereas that of C4B5 and HLA-DR4 was significantly increased only in the RF positive subgroup. The frequency of C4AQ0 was higher in the RF positive than in the RF negative subgroup (66.7% vs 27.3%, P < 0.05). Other clinical findings—such as gender, disease duration, clinical stage, presence of family history, rheumatoid nodule, or other extra-articular signs—were not associated with C4 allotypes, nor were the inflammatory variables.

Association of C4AQ0 and C4B5 with HLA

The frequency of HLA-DR4 was increased in rheumatoid patients compared with controls (60.7% vs 36.9%, P < 0.001, OR 2.6) (table 2). Association of C4AQ0 and C4B5 with HLA-DR4 was analysed in rheumatoid patients and controls (table 3). C4AQ0 did not show an association with HLA-DR4 and there was no significant difference in the frequency of C4AQ0 between DR4 negative and DR4 positive rheumatoid patients. The frequency of C4AQ0 was increased in DR4 negative patients compared with DR4 negative controls (P < 0.005). C4B5 was strongly associated with HLA-DR4 in both control and rheumatoid patient groups. The frequency of C4B5 allele was significantly higher in DR4 positive than in DR4 negative individuals in both control and patient groups (P < 0.001, P < 0.005 respectively). DR4 positive rheumatoid patients showed increased frequency of C4B5 compared with DR4 positive controls (P < 0.05).

HLA haplotypes carrying C4AQ0 and C4B5 were studied in 165 controls derived from family study material. C4B5 showed a strong linkage disequilibrium with HLA-B54 or B59, DR4, DQ4, and C4A3 and the most frequent extended haplotype was HLA-B54 or B59; BFS; C4A3; C4B5; DQ4 (13/24 C4B5 positive haplotypes). This allelic association was also that most commonly observed in C4B5 positive rheumatoid arthritis patients (8/19), although RF was not studied in the patient group. On the other hand, C4AQ0 showed a strong linkage disequilibrium with HLA-A33, B58, DR13, and DQ1 in healthy controls, and the most frequent extended haplotype carrying C4AQ0 was A33; Cw10; B58; BFS; C4AQ0; C4B1; DR13; DQ1 (6/15 C4AQ0 positive haplotypes). However, in rheumatoid patients, this allelic association was not observed and C4AQ0 did not show a significant association with any HLA class I or class II allele.

Discussion

In our study, the frequencies of C4AQ0 and C4B5 alleles were significantly increased in Korean patients with rheumatoid arthritis. This finding was also observed in a previous study of Japanese patients with rheumatoid arthritis,9 but in none of the studies of other ethnic groups.4 8 10 11 Thus far, a limited number of studies on the association between complement allotypes and rheumatoid arthritis has been reported in populations from the United States and Europe, and the results have
been controversial.\textsuperscript{2–4, 11} Association between allotypes of BFS,\textsuperscript{2–4} C4B3,\textsuperscript{2, 3, 4, 6, 7} C4A4,\textsuperscript{7} C4 null alleles,\textsuperscript{9} and rheumatoid arthritis has been reported.

In our study, we found that C4B5 was strongly associated with HLA-DR4 in both control and rheumatoid arthritis patient groups. DR4 positive rheumatoid arthritis patients showed higher frequency of C4B5 than DR4 positive controls (table 3), probably because of the association of C4B5 with certain subtypes of DR4 related to rheumatoid arthritis susceptibility in Koreans (DRB1*0405, unpublished observation). In comparison, C4AQO was not associated with HLA-DR4, and C4AQO was considered to be a DR4 independent rheumatoid arthritis susceptibility factor (table 3).

We found an interesting relation between RF and complement C4AQO, C4B5, and HLA-DR4 in rheumatoid patients (table 2). The frequencies of C4B5 and HLA-DR4 were significantly increased only in the RF positive subgroup. The frequency of C4AQO was significantly increased in both the RF positive subgroup (27.3%) and the RF negative subgroup (66.7%) and more markedly increased in the latter. Although the number of RF negative patients was rather small in our study, this finding suggests that C4AQO is an independent risk factor determining rheumatoid arthritis susceptibility in Koreans, and might play an important role, especially in RF negative patients.

Thus far, reported positive associations of complement allotypes with rheumatoid arthritis have mostly involved certain haplotypes bearing both HLA-DR4 and C4B3 or BFS.\textsuperscript{2, 3, 5, 7} In the present study, C4AQO was not associated with HLA-DR4, and a disease susceptibility allele in linkage disequilibrium with C4AQO is suggested in Korean patients with rheumatoid arthritis. It is interesting that C4AQO\textsuperscript{6} confers disease susceptibility to rheumatoid arthritis in the Japanese\textsuperscript{9} and Koreans, who have very similar genetic backgrounds in terms of their HLA and C4 types.\textsuperscript{10, 11} Hillarby et al.\textsuperscript{10} reported associations of C4AQO with vasculitis and C4BQ with Felty syndrome among rheumatoid arthritis patients. DR4 positive rheumatoid arthritis patients. We could not find such associations in the present study, in which the numbers of patients with extra-articular disease were rather small.
