The association between fibromyalgia and carpal tunnel syndrome in the general population

Fibromyalgia and carpal tunnel syndrome are common diseases in adult women. Their prevalences in the whole population are 2% and 9.2%, respectively. Recently, a study performed in northern Spain has suggested that the two conditions are often associated, with patients with fibromyalgia showing evidence of carpal tunnel syndrome. This 16% prevalence for the association is higher than that observed for carpal tunnel syndrome alone and suggests that common underlying mechanisms are at work. However, the study was done on patients referred to the clinic for fibromyalgia and no data are known about the occurrence of the association in the general population. During a survey on the prevalence of peripheral pain in an Italian population sample, we came across several patients with fibromyalgia or carpal tunnel syndrome and have studied the occurrence of the association between the two conditions.

A postal questionnaire was sent to 4456 subjects living in Chiavari, northern Italy, to investigate the presence of articular signs and symptoms. Subjects were asked to report if they had any joint pain or swelling for more than four continuous weeks and if they currently had joint pain or swelling, by indicating the relevant sites on a mannequin. In addition, they were asked to report the presence of morning stiffness lasting more than 30 minutes. This set of questions was originally developed by the ARC Epidemiology Unit in Manchester, United Kingdom and its primary goal was to detect prevalent cases of rheumatoid arthritis.

The diagnosis of fibromyalgia was based on the criteria suggested in 1990 by the American College of Rheumatology. That is, widespread pain and the presence of tenderness in at least 11 of 18 sites (tender points).

The diagnosis of carpal tunnel syndrome was made on clinical grounds. It included (a) history of numbness, paraesthesia, and/or pain in the fingers innervated by the median nerve, and (b) positive Tinel sign or positive Phalen sign. Invasive tests, such as nerve conduction studies, were not performed in view of the epidemiological nature of the research.

After two mailings, 2440 out of 4456 subjects (54.8%) returned the questionnaire. Of these, 182 (7.5%) had joint pain and swelling in at least two joints. This group of patients was offered a clinical examination; 93 (51.1%) agreed to be visited. Fibromyalgia was present in 21 (22.6%) of these patients and carpal tunnel syndrome in 26 (28%). Both conditions occurred simultaneously in nine patients (9.7%) (table). The odds ratio was 2.4 (95% confidence interval 0.9 to 6.8). These fibromyalgia-carpal tunnel syndrome patients were older (44.5 ± 13.2 years) than that observed for fibromyalgia alone and carpal tunnel syndrome. The mean number of tender points was obviously higher in patients with fibromyalgia than in those with carpal tunnel syndrome alone (33.2 ± 8.3; P < 0.001). Self reported joint swelling and early morning stiffness were more frequently distributed in the three groups of patients.

Our data show that respondents who reported a history of joint pain and swelling of peripheral joints were often affected by fibromyalgia or carpal tunnel syndrome. This study does not disclose the absolute prevalence of fibromyalgia and carpal tunnel syndrome because the questionnaire was intended for screening patients with possible rheumatoid arthritis that were not those with fibromyalgia or carpal tunnel syndrome. However, in a pilot study, most of the outpatients with these conditions attending a rheumatological clinic were asked positively to the questionnaire. We believe that patients with fibromyalgia reported articular involvement on the mannequin because they were unable to differentiate articular from extra-articular pain. In addition, they frequently over-reported swelling. Patients with carpal tunnel syndrome as a rule complain of pain and numbness associated with a subjective sensation of swelling in the hands, especially in the morning. Both fibromyalgia and carpal tunnel syndrome are characterised by morning stiffness.

In addition, there is the possibility of a selection bias due to over-representation of patients with more severe symptoms. Since this subgroup is more likely to respond to questionnaires. A further limitation of this study was that the same observer performed the Tinel and Phalen tests and pressed tender points. Therefore, information bias cannot be excluded. Both biases would increase the strength of this association. Nevertheless we feel that the magnitude of the association between fibromyalgia and carpal tunnel syndrome is the general population.
