Steroids cause osteoporosis

We read with great interest the article by Gudbjornsson and colleagues and concur with the accompanying leader by Dr Paget on the issue of corticosteroid associated osteoporosis. Osteoporosis is a major public health problem, associated with significant morbidity and mortality, and is estimated to cost £614 million annually in England and Wales alone. Despite well published guidelines on the prevention and treatment of corticosteroid associated osteoporosis, as a profession, we are failing to meet the targets set by these guidelines.

In the light of the American College of Rheumatology guidelines of 2001, we performed an audit of our current practice relating to the issue of steroid prescription, calcium supplementation, measurement of bone density, and the prescription of anti-resorptive treatment to see if we had been adhering to the recommendations of the National Osteoporosis Society. Our rheumatology department has a continually updated database on all current and past patients who have attended our unit. This contains information on patient demographics, primary rheumatological diagnosis, comorbid conditions, current drug treatment, past disease modifying treatment (including corticosteroids), and records all patient generated events, including outpatient and inpatient episodes. From our database of over 10,000 patients, we identified 258 patients who were currently receiving prednisolone and had been taking the drug for a minimum of three months.

Forty patients were selected at random and case records were then reviewed. We recorded information on patient demographics, current prednisolone dose, the maximum prednisolone dose, and the reason for the prescription of corticosteroids. We looked at other identifiable risk factors for osteoporosis, the co-prescription of calcium supplements and treatment for osteoporosis and whether the patients had ever had a bone density measurement. Finally, we telephoned a selection of the patients to inquire if they had ever received verbal or written information on osteoporosis.

If you have a burning desire to respond to a paper published in the Annals of the Rheumatic Diseases, why not make use of our "rapid response" option?

Login to our website (www.annrheumdis.com), find the paper that interests you, and send your response via email by clicking on the "eLetters" option in the box at the top right hand corner. Providing it isn’t libelous or obscene, it will be posted within seven days. You can retrieve it by clicking on "read eLetters" on our homepage.

The editors will decide as before whether also to publish it in a future paper issue.

For many years, we have been aware that our patients who are on steroids for a long time need to be managed properly. We are concerned that, despite the warnings of our colleagues, we are still not getting the message across. We do not know the proportion of patients who have been treated, but we do know that almost 20% have not received any form of treatment.

Forty patients (29 female) were randomly selected. The median patient age was 63 years (range 33–85). The patients were taking a mean daily dose of 6.7 mg prednisolone (range 1–45) and had been prescribed prednisolone for a median of 6 years (range 3 months–20 years). The most common reason for the prescription of prednisolone was for polymyalgia rheumatica for 14 (35%) of those selected, followed by systemic lupus erythematosus (SLE) in nine (23%), rheumatoid arthritis or associated complications for four (10%), and mixed connective tissue disease for three (8%). There were also isolated prescriptions for juvenile idiopathic arthritis, dermatomyositis, polymyositis, psoriatic arthritis, Wegener’s granulomatosis, iritis, and unspecified systemic vasculitis.

Encouragingly, 34 (85%) of our cohort were receiving some form of bone protective treatment: 22 (55%) were taking an oral bisphosphonate and one patient received intravenous pamidronate. Four of the postmenopausal women were taking hormone replacement therapy and two patients were receiving calcitriol. Twenty (50%) were prescribed calcium and vitamin D. Twelve of the 20 patients who were not taking these agents had osteoporosis. Seventy (175%) were taking anti-resorptive agents, and this was the only treatment in eight (20%) of the cohort. However, of the six patients not receiving any form of bone therapy, five were over the age of 65 years and the one patient under the age of 65 years was taking prednisolone continued for 20 years for SLE, up to a maximum dose of 80 mg/day.

Twenty four (60%) of the 40 patients had bone density measured by dual x-ray absorptiometry (DXA) scan. Of these, seven (29%) were normal, eight (33%) showed osteopenia, and nine (38%) demonstrated osteoporosis at the lumbar spine or the neck of the femur, or both. All patients who had either osteopenia or osteoporosis received treatment with prednisolone. Four of the patients who had a DXA scan were not receiving any form of bone protective treatment.

We interviewed 24 patients by telephone. Eighteen (75%) recalled being informed of steroid side effects. Seven had received written information on steroids, but only three had received written information on osteoporosis. Although our results are encouraging, a significant number of patients are not being treated to prevent osteoporosis and reduce future fracture risk. The fact that all patients with an abnormal bone density scan are treated is reassuring, but we cannot be sure what proportion of patients who have not been scanned require treatment. In 1996, Walsh and colleagues found that only 14% of patients receiving long term prednisolone were receiving some form of preventive treatment against osteoporosis. Although matters have improved to a degree, a substantial proportion of patients treated with steroids is still undertreated and considerable progress has to be made nationally and internationally to prevent further bone associated morbidity among patients treated with corticosteroids.

References

Walsh LJ, Wong CA, Pringle M, Tattersfield AE. Use of oral corticosteroids in the community and the prevention of steroid-induced osteoporosis. They also reported their experience at their rheumatological clinic with more than 10,000 patients. Surprisingly, only 2.6% of their patients were receiving bisphosphonate, but unfortunately they did not report whether this was primary or secondary prevention or treatment against manifest osteoporosis, nor did they report the prevalence of fragility fractures in their patient group. Although this is a much higher proportion than we and others have previously reported, still 20% of their patients were not treated with any antiresorptive agent and 15% were neither receiving specific bone protective treatment nor calcium or vitamin D supplementation.

These figures show that even in a specialist clinic with attention to osteoporosis, further work needs to be done in primary prevention against steroid-induced osteoporosis. Since we performed our study in northeastern Iceland, an Osteoporosis Clinic with DXA has been established in the study area, and the Directorate of Public Health in Iceland has published clinical guidelines concerning this issue. Thus, it will be of interest to re-perform our study in the near future for evaluation of the actual improvement in preventing bone morbidity in patients in need of long term treatment with corticosteroids.

Sjögren's syndrome criteria

In the June issue of the Annals Manthorpe comments on the recently proposed US-European consensus criteria for Sjögren's syndrome (SS).1 We would like to deal with some of the issues he raises, and add some comments.

Not all the classification criteria have evolved from rather subjectively biased ones to more objective assessments, it is surprising that the two most disease-specific objective parameters currently available for SS are subject to rather subjective criticism. Of course, when serological and histological items are emphasised in the new SS classification criteria, their individual disease sensitivity and specificity should always be kept in mind.

In fact, all six items that are included in the classification criteria may be subject to discussion. For example, the Schirmer-I test, and unstimulated whole saliva flow test have been criticised in a number of papers,6,7 but these items are recommended in Manthorpe's paper.

Manthorpe expresses his concerns about the accuracy of sublabial salivary gland biopsies (SLGBs), referring to one paper in which a change of diagnosis of >50% is reported after a second examination of the SLGBs. However, the authors themselves report that not using the focus scoring system was probably the most important reason for the change of diagnosis on the second examination. They did not conclude that the focus score itself—which is mandatory to fulfil item VI—changed dramatically upon re-examination of the specimens!8

Other ways of bypassing interobserver variability are also available—for example, measuring two parameters instead of one (for example IgA% and focus score) provides a synthetic score for the accuracy of diagnosis,9 and, moreover, computer aided scoring methods may provide non-observer dependent data. For measuring the IgA% reliably and reproducibly objective data from the biopsies are obtained by combining microscope, computer, and calibrated software. These biopsies show what is going on in the target organs of this disease and may provide early diagnostic markers; one should not put them aside too easily.

Manthorpe also criticises the SS classification criteria for the interdependent relation between anti-Ro/anti-La antibodies (item IV) and the focus score (item VI). They are certainly associated with each other, but why is that a problem? The worldwide accepted American Rheumatism Association criteria for rheumatoid arthritis also contain interdependent items—for example, positive rheumatoid factor serology is generally considered as strongly associated with erosions of articular joints and joint damage. Interdependency can also be found in the American College of Rheumatology classification criteria for systemic lupus erythematosus (presence of antinuclear antibodies is a distinct item from presence of anti-dsDNA or anti-Sm, items 11 and 10 respectively). Furthermore, it appears inconsistent that Manthorpe recommends including the pathohistological signs in the SS classification criteria. This would also introduce an interdependent item.

The dependency does not equal a one-on-one relation—that is, seronegative patients may have a positive focus score and vice versa. In particular, because numerous reports have shown that the focus score alone can be false positive or false negative,10 the presence of anti-Ro/anti-La antibodies which are still the most disease-specific and sensitive parameters available, has additional value for the accuracy of diagnosis. Finally, it has yet to be proved that the suggested new antibodies (anti-fodrin, anti-muscle) are more sensitive and disease-specific than the existing classic anti-Ro and anti-La antibodies. Therefore it is too early to include such items in classification criteria.

While our knowledge of Sjögren's syndrome increases, classification criteria may develop in a way that enhances early diagnosis of possibly reversible target organ damage. Therefore not the end stage symptoms and signs (items I–III and V) but rather the early target organ-specific and serological items are likely to retain their place in the classification criteria. Therefore, in our view the US-European consensus group is right to emphasise items IV and VI, which should not be neglected in the search for better alternatives have been introduced.

M. M. Zandbelt, F. H. J. van den Hoogen
Department of Rheumatology, University Medical Centre Nijmegen, The Netherlands

Manthorpe also criticises the criteria that patients with genuine SS do not complain of dry eyes because the cornea—although heavily innervated—lacks nerves that register dryness. This makes item I in the proposed criteria set invalid and should have been changed.

As far as smoking is concerned, it seems of great importance that clinicians know such details just as they know the medical history. When did smoking start and stop? What was the weekly consumption of cigarettes? Patients, who are present or past smokers, and who have at least two abnormally low test results from both the main affected exocrine organs, lachrymal and salivary glands, very often lack circulating anti-SSA/B autoantibodies. We have known for some years that patients with genuine SS do not complain of dry eyes because the cornea—although heavily innervated—lacks nerves that register dryness. This makes item I in the proposed criteria set invalid and should have been changed.

Author's reply

Zandbelt and van den Hoogen raise and discuss some important issues put forward in the June Leader of the Annals concerning Sjögren's syndrome (SS) criteria published by a consensus group consisting of European and North American SS experts.1 I agree with them that final diagnostic criteria will be set up as research tools, but nevertheless find their way into daily clinical practice. I am of the opinion that it is best to have as few preliminary classification criteria as possible. When coming up with new proposals these should include changes that are due to date in all aspects, otherwise other proposals will arise too soon. It is here, among other things, that I am disappointed by the consensus group's latest proposal.

Most SS specialists agree that it is difficult to diagnose SS without close collaboration between clinical specialists within ophthalmology, oral medicine/oral surgery, and rheumatology. The US-Eur proposal is written by 3 authors but not a single person is an ophthalmologist! We have known for some years that patients with genuine SS do not complain of dry eyes because the cornea—although heavily innervated—lacks nerves that register dryness. This makes item I in the proposed criteria set invalid and should have been changed.

References

patients would not be diagnosed as having SS if the US-Eur criteria were followed. Given that the patient in question is a present or past smoker should lead to the consequence that a smoker should lead to the same conclusion. The history of most SS patients has been found. Classification criteria should not, therefore, concentrate solely upon the SSA/B autoantibodies but be open to newer ones as well. As mentioned in the SSA/B autoantibodies (item IV) cannot be trusted and consequently should be disregarded. Best results in personal family consequences it might have great social effects in some countries. In Sweden, for example, patients might get their dental repair bill subsidised by the State if they have SS diagnosed according to the Copenhagen criteria and, in addition, have abnormal unstimulated and stimulated whole sialometry, measured by 15 and 5 minutes, respectively.

I agree with Zandbelt and van den Hoogen that the original set of SS criteria, the Copen-

crera (also termed Japanese III), which look simultaneously present their new classification cri-
tera would seem to have a rather short timespan and therefore it may not pay to focus score

A brief history of spa therapy

We read with great interest the paper entitled “A brief history of spa therapy” by van Tuber-
gen and van den Hoogen in the March edition of the Annals. Spas have certainly played an important part throughout the centuries not only in recreation but also in restoring physical and mental health. International and local doctors have greatly influenced the progress of rheumatology—for example, Bruce from Scotland described polymyalgia, Forester introduced gold treatment for rheumatoid arthritis in France, and Sita and Zitnan from Piestany described polychrystalline chondrocalcinosis.

We regret that this paper failed to mention the famous spas of the Czech Republic, Slovakia, Hungary, and Romania. From their conception, Czech and Slovak spas became gathering places not only for aristocrats but also for kings and emperors. Hungary, one of the richest countries of thermal waters in the world, has a bath culture dating back to the pre-Roman Celtic times. Budapest is a capital unique for its thermal waters. It is also renowned for Lake Divci, the second bigger hot lake in the world, second to Rotorua, New Zealand.

We are proud to have published in English the first double blind controlled trials with thermal waters. Hungary is the only country where medical use of thermal waters is practised based on its efficacy proved in controlled trials.

We profoundly disagree with the authors, that “taking the water, balneotherapy, spa therapy, hydrotherapy are more or less inter-

changeable”. We are certain that they are not. Even in their paper, they quote Priesnitz and Kneipp, who distinguished between thermal water (balneotherapy) and hydrotherapy. Hydrotherapy uses only the physical qualities of water (buoyancy of water, resistance, sometimes its temperature (cold or warm), whereas thermal waters are not only naturally warm (>20°C) but their mineral content is also significant. In Hungary a recognised min-
eral water should have minerals 1 g/l or more, but no nitrates, nitrates, or bacterial growth. It is not known whether the minerals of mineral water penetrate the body surface, but they are known to cause a so-called spa or mineral water reaction. The mineral water reaction includes tiredness and fatigue especially after 5-8 baths with an associated rise in the leucocyte count and erythrocyte sedimentation rate even within the normal range. The mineral water reaction passes away after 5-10 baths, and the optimal “taking the waters” is a total of 15-22 baths taken daily.

There is no equation between thermal min-
eral waters and spa therapy either. As we pointed out in a debate in the columns of the Journal of Rheumatology the effect of thermal mineral waters and the effect of complex spa therapy should be distinguished. We performed our double blind trials on inhabitants of ordinary Hungarian towns and villages with no spa facilities to exclude the placebo effect of a change in environment, physio-
therapy, and being in a holiday atmosphere. In spa surroundings no double blind trials can be done. The results of follow up of these subjects suggest that non-spa treatment can be used as a control for future studies. Furthermore, the effect of spa water and heated tap water can be used for local residents to exclude the pla-
CEO effect of spa atmosphere, associated physiotherapy. If we want to have evidence based proof for thermal mineral water or spa treatment, or both, we should keep strictly to these rules.

We agree that spa resorts are excellent places for the rehabilitation of patients with rheumatic diseases, especially ankylosing spondylitis. In addition, rehabilitation treat-
ments are available for patients with fibro-
myalgia, a group who are frequent users of spa facilities. Most of the German, Czech, Slo-
vak, Hungarian, and Russian spas also func-
tion as rehabilitation centres. In Hungary, thermal mineral water and spa treatment is a recognised treatment for rheumatic patients, although hard data are lacking. The Hungar-
ian government has launched a 10-year spa programme for the development of Hungarian spas. In addition, the Hungarian National Activity Network of the Bone and Joint Decade was given the task by the minister of health to start evidence-based research about the effect of mineral water and spa treatment. Hungary organises the 34th World Congress of the International Society of Medical Hydro-
logy and Climatology at Budapest and Hévíz in October this year. Attendance by rheumatolo-
gists and rehabilitation experts is expected. We feel it is time to create European co-operation in rheumatology spa and mineral water research. We are convinced that multicentre trials would be suitable and could eliminate differences in mineral concentration, tem-
peratures, cultures and beliefs. Underdevelop-
ment of evidence-based physiotherapy is partly due to lack of funding for necessary trials. The situation is similar in the case of therapy and spa treatment trials. This problem may be overcome by conducting multicentre trials in many countries. Such trials may result in an evidence-based approach to therapeutic or recreational bathing.

Authors’ reply

We thank the Drs Bender, Balint, and Balint for their comments on our study and their additional remarks. We did not intentionally exclude the spas in countries such as the Czech Republic, Slovakia, Hungary, and Romania. In our paper we provided some exam-
pies of spas in European countries which we had found mentioned in published reports. We are, however, well aware of the central role of spas elsewhere in the world both in the past and the present and their major role in the development of rheumatology as a medi-
cal profession. 1, 2

We fully agree that because spa therapy has an important role in rheumatology in many countries more research should be done and...
also support the idea of multicentre studies. We regret, and we have experienced this, that those who finance research projects are extremely reluctant to fund trials in this field. We hope that, as has been suggested, with the creation of European cooperation in rheumatology and mineral water research we will be able to provide strong scientific evidence for the effectiveness of spa therapy in the near future.

BOOK REVIEW
Pathological basis of orthopaedic and rheumatic disease

The author provides an overview of the pathology of orthopaedic and rheumatoid diseases which could help pathologists in finding the correct diagnosis and also support clinicians and rheumatoid disease oriented researchers in obtaining information about a broad range of distinct pathological disorders. There are eight chapters starting with skeletal structure development and progressing to injuries, infections, disorders of the skeletal development, and metabolic and other generalised diseases of the skeleton. Final chapters deal with diseases of articular tissues, including osteoarthritis and rheumatoid arthritis, and also describe tumours and tumour-like lesions of bone and soft tissue. The last two chapters covering tumour pathology comprise 40% of the content.

Each chapter stands by itself and, therefore, it is possible to focus directly on the matter of interest. The structure of description of the particular disease is consistent and logical and helpful to the reader. The normal format is a short introduction to the disease, some clinical features, radiological features, gross pathology, and histopathology. Every chapter ends with a list of references. The author quotes more than 1500 citations. More than 250 figures including histology, gross pathology, radiological pictures, and schematic diagrams and many tables enrich the quality of the volume.

In a future edition, inclusion of colour figures and an indication of the magnification of the histology pictures would be helpful. From our point of view working in the field of rheumatoid arthritis, the subchapter dealing with the disease could be extended, because the incidence of rheumatoid arthritis is 1–3% in Western countries.

What is missing is any reference throughout the text to the molecular and cellular mechanisms of the diseases. However, we suggest that this single volume would be useful for everyone interested in a summary of histological features of numerous orthopaedic and rheumatic diseases as seen in the clinic.
