ABSTRACT

Objectives To compare the efficacy and safety of innovator infliximab (INX) and CT-P13, an INX biosimilar, in active rheumatoid arthritis patients with inadequate response to methotrexate (MTX) treatment.

Methods Phase III randomised, double-blind, multicentre, multinational, parallel-group study. Patients with active disease despite MTX (12.5–25 mg/week) were randomised to receive 3 mg/kg of CT-P13 (n=302) or INX (n=304) with MTX and folic acid. The primary endpoint was the American College of Rheumatology 20% (ACR20) response at week 30. Therapeutic equivalence of clinical response according to ACR20 criteria was concluded if the 95% CI for the treatment difference was within ±15%. Secondary endpoints included ACR response criteria, European League Against Rheumatism (EULAR) response criteria, change in Disease Activity Score 28 (DAS28), Medical Outcomes Study Short-Form Health Survey (SF-36), Simplified Disease Activity Index, Clinical Disease Activity Index, as well as pharmacokinetic (PK) and pharmacodynamic (PD) parameters, safety and immunogenicity.

Results At week 30, ACR20 responses were 60.9% for CT-P13 and 58.6% for INX (95% CI −6% to 10%) in the intention-to-treat population. The proportions in CT-P13 and INX groups achieving good or moderate EULAR response criteria, change in Disease Activity Score 28 (DAS28), Medical Outcomes Study Short-Form Health Survey (SF-36), Simplified Disease Activity Index, Clinical Disease Activity Index, as well as pharmacokinetic (PK) and pharmacodynamic (PD) parameters, were statistically similar. Secondary endpoints included ACR response criteria, European League Against Rheumatism (EULAR) response criteria, change in Disease Activity Score 28 (DAS28), Medical Outcomes Study Short-Form Health Survey (SF-36), Simplified Disease Activity Index, Clinical Disease Activity Index, as well as pharmacokinetic (PK) and pharmacodynamic (PD) parameters, safety and immunogenicity.

Conclusions CT-P13 demonstrated equivalent efficacy to INX at week 30, with a comparable PK profile and immunogenicity. CT-P13 was well tolerated, with a safety profile comparable with that of INX.

ClinicalTrials.gov Identifier NCT01217086

INTRODUCTION

Innovator infliximab (INX), a chimeric monoclonal antibody to tumour necrosis factor-α (TNFα), with demonstrated beneficial effects in rheumatoid arthritis (RA) patients, was approved in 1999. The approval of INX was based on data from the ATTRACT study.1 The availability of targeted biological therapies has revolutionised the treatment of RA. However, the significant cost of these medications creates a major barrier that limits universal access to these effective therapeutic agents. This has led to interest in developing biosimilar products, which are highly similar, but not identical and not “bioidentical”, to approved “reference” agents.2

CT-P13 is an immunoglobulin (Ig)G1 chimeric human–murine monoclonal antibody biosimilar to INX. CT-P13 is produced in the same type of cell-line (Sp2/0-AG14—produced from ATCC, Cat. CRL-1581) and has an identical amino acid sequence to approved INX. CT-P13 and INX have demonstrated comparable in vitro primary pharmacodynamics (PD) in a range of studies (CELLTRION, Inc unpublished data; see online supplementary appendix A). CT-P13 and INX showed comparable binding affinities to monomeric and trimeric forms of human TNFα (hTNFα), transgenic mouse hTNFα (tmhTNFα) expressed by Jurkat cells and to Fcγ receptors and FcRn. Comparable hTNFα neutralising activity against a TNFα-sensitive mouse sarcoma cell-line (WEHI-164) has also been demonstrated. CT-P13 and INX are also comparable in terms of: lack of binding activity with hTNFβ and TNFα from a range of different species known not to bind infliximab; relative binding affinities to complement protein C1q; complement dependent cytotoxicity effects and apoptotic effects against a Jurkat T cell-line expressing tmhTNFα.

Comparable cytotoxic activities have been achieved as a result of antibody-dependent cellular cytotoxicity evaluation of human peripheral blood mononuclear cells against tmhTNFα–Jurkat T cells, demonstrating biosimilarity of CT-P13 and INX. Highly comparable human tissue cross-reactivity results have been observed for biotinylated CT-P13 and biotinylated INX. CT-P13 was also assessed for bioequivalence to INX in a phase 1 trial in ankylosing spondylitis (AS).1
Based on the data described, this trial, PLANETRA (Programme evalutaing the Autoimmune disease ivNeVestigational drug cT-p13 in RA patients), was conducted with the approval of the regulatory authorities including EMA. PLANETRA was designed to assess efficacy equivalence and to evaluate pharmacokinetics (PK), PD and overall safety of multiple doses of CT-P13 versus INX in active RA patients.

**PATIENTS AND METHODS**

**Patients**

Patients with active RA according to the revised 1987 American College of Rheumatology (ACR) classification criteria for ≥1 year prior to screening were recruited. Patients had to have ≥6 swollen and ≥6 tender joints and at least two of the following: morning stiffness lasting ≥45 min; serum C reactive protein (CRP) concentration >2.0 mg/dl and erythrocyte sedimentation rate (ESR) >28 mm/h despite methotrexate (MTX) therapy for ≥3 months (stable dose of 12.5–25 mg/week for ≥4 weeks prior to screening). Patients were permitted to receive both oral glucocorticoids (equivalent to ≤10 mg daily prednisolone) and non-steroidal anti-inflammatory drugs, if they had received a stable dose for ≥4 weeks prior to screening. Additional details of patient eligibility criteria are provided online (see online supplementary appendix B).

**Study design**

The study (ClinicalTrials.gov NCT01217086) was conducted according to the Declaration of Helsinki and the International Committee on Harmonisation good clinical practice. The protocol was reviewed and approved by regulatory authorities and the ethics committees of each study site. Written informed consent was obtained from all patients. The study was conducted at 100 centres across 19 countries in Europe, Asia, Latin America and Middle East.

Patients were randomly assigned 1:1 to receive 2 h intravenous infusion of either 3 mg/kg of CT-P13 (CELLTRION INC, Incheon, Republic of Korea) or INX (Janssen Biotech Inc, Horsham, Pennsylvania, USA) at weeks 0, 2 and 6 and then

q8 weeks up to week 30. Patients were premedicated with anti-
histamine (chlorpheniramine 2–4 mg or dose of equivalent anti-
histamine) 30–60 min prior to the start of infusion at the
investigator’s discretion. Weekly MTX (12.5–25 mg/week, oral
or parenteral dose) and folic acid (≥5 mg/week, oral dose) were
coadministered. Rescue therapy was only allowed with tramadol
and/or acetaminophen. Salvage therapy was defined as an anti-
rheumatoid drug, such as disease-modifying antirheumatic
drugs, non-steroidal anti-inflammatory drugs and any biological
agent for the treatment of RA, received on or after the day of
the first dose of study treatment.

Study endpoints
The primary endpoint was to demonstrate equivalent efficacy
of CT-P13 to INX at week 30, as determined by ACR20 response
criteria. Equivalence of efficacy was concluded if the 95% CIs
for treatment difference were within ±15% at week 30.

Secondary endpoints included additional efficacy, immuno-
genicity, safety, PK and PD parameters. Clinical assessments of
disease activity, including the additional measures: ACR individ-
ual component scores; ACR20/ACR50/ACR70; time-to-onset of
ACR20; mean decrease in Disease Activity Score 28 (DAS28);
European League Against Rheumatism (EULAR) response cri-
teria; Clinical Disease Activity Index (CDAI); Simplified Disease
Activity Index (SDAI) and general health status (Medical
Outcomes Study Short-Form Health Survey (SF-36)), were per-
formed before infusion at baseline, weeks 14 and 30. A post
hoc analysis of ACR-EULAR remission rate at week 30 was also
performed. 4

Blood samples collected at screening and weeks 14 and 30
were assessed for antidrug antibodies (ADA), and a post hoc
analysis of endpoints by ADA status was conducted. Immuno-
genicity testing used both the CT-P13 tag and INX tag
(see online supplementary appendix C). Antibodies against
CT-P13 or INX were measured using an electrochemilumines-
cent immunoassay method using the Meso Scale Discovery plat-
form (MSD, Rockville, Maryland, USA).

Safety endpoints included incidence and type of adverse
events (AEs) and infection, serious AEs, incidence of infusion-
related reactions and changes from baseline in clinical laboratory
parameters. AEs were coded using the Medical Dictionary for
Regulatory Activities and severity was characterised as mild,
mild, moderate or severe.

All patients were screened for latent or active tuberculosis
(TB) by an interferon γ-release assay using Quantiferon-TB
Gold in tube (QFT-TB Gold-IT, Cellestis, Australia) and
chest x-ray and monitored for any clinical signs and symptoms
of TB at each planned visit. Patients with latent TB received
prophylactic medication before and during the study period
according to country-specific guidelines. For countries with an
increased incidence of TB, QFT-TB Gold-IT was used at weeks
14 and 30 to identify positive conversion from negative results
at baseline, according to WHO recommendations for sole use of
interferon γ-release assay in non-HIV adults receiving anti-TNF
therapy. 5 6

PK endpoints included Cmax, Cmin, Cavg, peak to trough fluctu-
tion ratio and time to reach Cmax (Tmax). PD endpoints
included concentrations of serum CRP, rheumatoid factor (RF)
and anticyclic citrullinated peptide (anti-CCP) and ESR. Serum
blood samples were obtained immediately before each dosing
for PK and PD analyses, and at the end and 1 h after the end of
each treatment infusion for PK analysis. All PK analyses were
conducted using a flow-through immunoassay platform
(GyrolabxP; Gyros AB, Sweden).

Figure 1 Flowchart of patient disposition. A total of 1077 patients were screened for the study, and 606 eligible patients were randomised into a
CT-P13 group (N=302) or an innovator infliximab (INX) group (N=304) to receive 3 mg/kg of CT-P13 or INX, respectively, coadministered with
methotrexate (MTX) and folic acid. All 606 randomly assigned patients were included in the intention-to-treat population. A total of 107 out of 606
randomised patients were excluded from the per-protocol population due to the various protocol violations. *Eleven patients from a potentially
fraudulent study site were excluded from analyses.
Statistical analysis
Sample size was determined using the following criterion: therapeutic equivalence to INX in the all randomised population was based on expected responder rates of 50% in the test and control groups. Specifying a two-sided \( \alpha \) level of 0.05, power of 80% and a two-sided equivalence margin of 15% required 468 patients in the per-protocol (PP) population final analysis. Assuming exclusion of 20% of patients from the PP population, this required a minimum of 584 randomised patients. In an equivalence trial, we conclude that two treatments are equivalent if the observable difference (\( \Delta_k \)) between them lies within an established interval for predefined clinical equivalence margin, \( (-d, d) \). The ‘null hypothesis’ is that the difference \( \Delta_k \) is outside of the equivalence margin, that is, either \( \Delta_k > d \) or \( \Delta_k < -d \). If collected data on the true difference \( \Delta_k \) reject the null hypothesis of ‘non-equivalence’ then we can accept the alternative explanation \( (-d \leq \Delta_k \leq d) \) that the two treatments work equally well.

All primary efficacy analyses were performed on both the intention-to-treat (ITT) and PP populations. All other efficacy analyses were performed on the PP population only. The proportion of patients achieving ACR20 response at week 30 was analysed by the exact binomial approach, calculating a point estimate and 95% CIs for the difference in proportion between the two treatment groups. The equivalence margin within \( \pm 15\% \) at week 30 was selected based on recommendations from regulatory bodies and historical data from clinical trials of INX plus MTX in RA. A weighted average for the treatment difference in ACR20 response between the INX plus MTX and placebo plus MTX was nearly 30%, and so the equivalence margin of 15% was considered appropriate.

A sensitivity analysis considering stratification factors was also performed, accounting for region (EU or non-EU) and serum CRP (\( \leq 2 \text{mg/dl} \) or \( > 2 \text{mg/dl} \)). The exact binomial and sensitivity analyses were repeated for the secondary ACR response criteria. Time-to-onset of ACR20 response was analysed by survival analysis. Descriptive statistics for change from baseline were presented from baseline were presented by randomised treatment group and study visit for DAS28, EULAR response, SDAI, CDAI and SF-36 subscales.

An analysis of covariance for DAS28 was performed with treatment group as a fixed effect and baseline DAS28 score, region and CRP as covariates. A point estimate and 95% CI for the treatment difference were provided. The EULAR response criteria were analysed using a relative risk (RR) with 95% CI for the difference in proportion between the two treatment groups. The number of patients requiring salvage retreatment was summarised by randomised treatment group and visit.

Safety endpoints analysed in safety population consisted of all patients who received at least one (full or partial) dose of either of the study treatments during any dosing period. In this population, patients were included in the CT-P13 group for safety analyses, irrespective of their randomisation if they received at least one (full or partial) dose of CT-P13. The PK–PD population consisted of all patients who received either CT-P13 or INX during the 30-week blinded study period and had at least one PK–PD concentration data value. PK–PD parameters were summarised using quantitative descriptive statistics by actual treatment group and study visit.

RESULTS
Patients
The first patient was screened in November 2010; the last week 30 evaluation was performed in November 2011. Baseline demographics and disease status were comparable between treatment groups (table 1). Of the 606 randomised patients, 515 completed the 30-week study period and, of these, 16 patients were excluded from the PP population due to major protocol violations. Discontinuation in randomised patients was primarily due to AEs (8.9%) and patient withdrawal of consent (4.1%) (figure 1).

Efficacy
The primary endpoint, ACR20 response at week 30, was equivalent between treatment groups and achieved in 60.9% and 58.6% in ITT (n=606, 95% CI −6% to 10%) and 73.4%
and 69.7% in PP population (n=499, 95% CI −4% to 12%) for CT-P13 and INX, respectively (figure 2A).

Equivalent results were also shown for ACR responses in the PP population at weeks 14 and 30 (figure 2B,C) for CT-P13 and INX, respectively. ACR50 and 70 responses in the ITT population at week 30 were comparable (35.1% and 34.2% for CT-P13 and INX, respectively). Post hoc analysis by baseline CRP showed highly similar ACR20 responses in the ITT population for CT-P13 and INX, respectively (CRP >2 mg/dl: 61.9% and 58.5%).

Mean improvements from baseline for additional secondary efficacy endpoints including CDAI and SDAI (CT-P13 (25.2 and 25.8) vs INX (23.6 and 24.4) at week 30, respectively) were equivalent at weeks 14 and 30 between treatment groups (table 2). The proportion of patients achieving good or moderate EULAR responses (CRP) at week 30 was highly similar (CT-P13 85.8% vs INX 87.1%, RR=0.98, 95% CI 0.92 to 1.06). Low disease activity or remission according to DAS28-CRP was achieved in 40.9% and 39.0% with CT-P13 and INX, respectively (figure 3). The proportion of patients requiring salvage therapy at week 30 was also highly similar between CT-P13 (3.2%) versus INX (4.0%). The medians of time-to-onset of ACR20 for the two treatment groups were almost identical (median CT-P13, 99 days; INX, 100 days).

In addition, ACR/EULAR remission rates were comparable for CT-P13 and INX at week 30 (Boolean: 6.9% (17/248) and 6.8% (17/251); SDAI: 9.7% (24/248) and 9.6% (24/251)). Efficacy criteria were also analysed according to ADA status at week 30 (see online supplementary appendix D).

Overall, no statistically significant differences in responses between the two treatment groups were found.

**Immunogenicity**

Antibodies to infliximab were detected using INX tag in 25.4% (n=69) and 25.8% (n=70) of patients for CT-P13 and INX at week 14 and 48.4% (n=122) and 48.2% (n=122) of patients for CT-P13 and INX, respectively, at week 30.

**Safety**

Overall treatment-emergent AE (TEAE) rates were reported in 181 (60.1%) patients and 183 (60.8%) patients for CT-P13 and INX, respectively. TEAE rates considered related to study treatment were reported for patients, were attributable to the study treatment and most frequently reported for patients were—CT-P13: latent TB (positive conversion of QTF, n=13), increased ALT (n=12), increased AST (n=8) and a flare of RA activity (n=7); INX: latent TB (n=14), increased ALT (n=11), increased AST (n=8) and urinary tract infection (n=7). Two patients were withdrawn due to malignancies in the INX group (figure 1), breast cancer and cervix carcinoma.

 Patients with latent TB were recommended for prophylactic TB medication, and latent TB in patients receiving prophylactic TB medication did not convert to active TB. There were three cases of active TB in the CT-P13 group and none in the INX group (see online supplementary appendix E).

CDAI, Clinical Disease Activity Index; CRP, C reactive protein; HAQ, health assessment questionnaire; INX, innovator infliximab; SDAI, Simplified Disease Activity Index; SF-36, Short-Form Health Survey 36; SJC, swollen joint count; TJC, tender joint count.

Infusion-related reactions occurred in 20 (6.6%) and 25 (8.3%) patients for CT-P13 and INX, respectively. The proportions of infusion-related reactions for CT-P13 and INX groups were 6.7% (n=9) versus 13.3% (n=18) in ADA-positive group and 4.2% (n=6) versus 2.8% (n=4) in ADA-negative group, respectively. Serious TEAEs were reported in 30 (10.0%) and 21 (7.0%) patients for CT-P13 and INX, respectively (see online supplementary appendix F). There were no deaths reported during the study.

Pharmacokinetics and pharmacodynamics
The PK and PD endpoint results were highly similar for each treatment group. In the PK population, geometric means and peak serum concentrations (C_{max}) were highly similar after each infusion of study treatment for doses 1–6, as was the overall range of geometric means across all doses (CT-P13, range 83.9–111.9 μg/ml; INX, range 83.8–105.1 μg/ml). The mean secondary PK endpoints were highly similar for CT-P13 and INX (see online supplementary appendix G).

In the ADA-negative subset, geometric mean C_{max} values were 96.7 and 91.6 μg/ml (90% CI of ratio 97% to 115%), and C_{min} values were 1.9 and 1.8 μg/ml (90% CI of ratio 85% to 132%) for CT-P13 and INX at dose 5, respectively. In the ADA-positive subset, geometric mean C_{max} values were 85.1 and 76.7 μg/ml (90% CI of ratio 99% to 124%), and C_{min} values were 0.6 and 0.6 μg/ml (90% CI of ratio 82% to 107%) for CT-P13 and INX at dose 5, respectively.

CT-P13 and INX had comparable mean CRP (1.2 vs 1.1 mg/dl and 1.1 vs 1.0 mg/dl), ESR (32.8 vs 31.0 mm/h and 30.6 vs 32.1 mm/h), anti-CCP (186.5 vs 195.4 IU/ml and 189.8 vs 174.6 IU/ml), IgA RF (41.2 vs 45.8 IU/ml and 33.9 vs 38.3 IU/ml), IgG RF (40.5 vs 33.4 IU/ml and 33.5 vs 29.5 IU/ml) and IgM RF (90.0 vs 88.0 IU/ml and 83.9 vs 82.5 IU/ml) at weeks 14 and 30, respectively.

DISCUSSION
In this randomised, double-blind, multicentre, multinational, parallel-group, prospective PLANETRA study, we assessed the equivalence of efficacy and comparability of safety, PK and PD of multiple doses of CT-P13 (3 mg/kg) versus INX (3 mg/kg) administered up to week 30 in active RA patients with inadequate response to MTX treatment. Equivalence of efficacy was
demonstrated, and there was no clinically meaningful difference in safety data. Only comparability of PK data was shown in this study, as coadministration of MTX could affect PK data; PK bioequivalence has been assessed in a phase I study for ankylosing spondylitis patients in the absence of MTX.\(^3\)

The primary outcome, ACR20 response at week 30, was shown to be equivalent for CT-P13 and INX: the 95% CIs for treatment difference were within the predefined margins for equivalence of \(\pm15\%\). To ensure a credible comparison with existing INX data, the disease definition for enrolment in our study was identical to ATTRACT\(^1\) and a separate phase III trial of INX in RA\(^,12\) was similar to a further, more recent trial.\(^13\) The finding that baseline CRP levels in the equivalent INX arm of the ATTRACT study (3 mg/kg, every 8 weeks) were higher than in both groups of this study (3.1 vs 1.9 mg/dl), raising the possibility that our study had enrolled a population with less severe disease, led us to conduct a post hoc sensitivity analysis of patients with baseline CRP >2 or \(\leq2\) mg/dl for each parameter for the ANCOVA analysis. Both assumptions did not hold for anti-CCP, IgA RF, IgG RF and IgM RF, and valid conclusions for these parameters beyond investigating trends cannot be drawn.

It is also interesting to note that although CRP is regarded as the better marker of inflammation, ESR may have utility in reflecting disease severity.\(^{14,15}\) However, as ESR data are not available for ATTRACT or any other placebo-controlled INX plus MTX studies in the literature, we rely on assessment of CRP to ensure appropriate comparison of patient populations.

Although the point estimates of medians for time-to-onset of ACR20 were very similar, we have observed faster tendency of ACR 20 response among CT-P13 group compared with the INX group based on log-rank test result (\(p=0.02\)). ACR20 responses were measured only at weeks 14 and 30; therefore, we have a limitation to adapt statistical survival methods on a very small number of evaluation time points and conclude log-rank test results from our data.

Efficacy criteria were also analysed according to ADA status at week 30, and no statistically significant difference in responses between the two treatment groups was found. However, as this was a post hoc analysis, interpretation of these results should be done with care and to a limited extent.

In our study, PK and PD endpoint results were highly similar for each treatment group and antibody status had a minimal effect on the PK of infliximab. A difference was noted in the change from baseline in anti-CCP at week 30 and IgG RF at week 14. However, these two parameters are more indicative of disease severity rather than a direct marker of anti-TNF\(_\alpha\) effect. In addition, it should be noted that the assumptions of normality and homogeneity of variance were assessed for each parameter for the ANCOVA analysis. Both assumptions did not hold for anti-CCP, IgA RF, IgG RF and IgM RF, and valid conclusions for these parameters beyond investigating trends cannot be drawn.

The objective with regard to safety was to demonstrate comparability of CT-P13 and INX, not equivalence. Overall, CT-P13 was well tolerated, and its safety profile was comparable with INX. The rate of infusion reactions in both treatment groups was approximately 7.5%, lower than the 20% incidence listed in the INX product information, although the incidence of severe infusion reactions was 1.3%, slightly higher than the \(<1\%\) listed.\(^16\) The safety results were similar to those observed in the ATTRACT and ASPIRE trials.\(^1,17\) The incidence of active TB in patients receiving INX or CT-P13 in this study (0% and 1.0%, respectively) was similar to that described in ATTRACT (0.3%) and ASPIRE (0.5%)\(^17\) and was not considered significant, as 42% of patients in our study were from countries listed in WHO Global tuberculosis report as having higher TB incidence,\(^18\) whereas ATTRACT and ASPIRE included only centres in North America and Western Europe.\(^1,17\)

Immunogenicity testing demonstrated a comparable profile for CT-P13 and INX in terms of proportion of ADA-positive patients at weeks 14 and 30. Although the proportion of ADA-positive patients was slightly higher than that observed in previous studies,\(^4\) the method used to detect immunogenicity was more sensitive than those previously used, and the proportion of ADA-positive patients was similar to that observed in more recent studies of INX.\(^19,20\)

Assessment of efficacy and safety of CT-P13 in patients with RA for up to 1 year is ongoing, and the positive results of this study provide a rationale for future studies of CT-P13 in the treatment of other TNF-mediated inflammatory diseases.

**CONCLUSIONS**

CT-P13 and INX were shown to be equivalent in terms of ACR20 response at week 30 in active RA patients with inadequate response to MTX treatment. Overall, CT-P13 was well tolerated and the safety profile of CT-P13 was comparable with that of INX.

</tbody>
</table>

The total number of treatment-emergent adverse events included all related patient events. At each level of summation, a patient was counted once if he or she reported one or more related events. Only the most severe event was counted. *Patients who received at least one full or partial dose of CT-P13 were included in the CT-P13 group for safety analyses, irrespective of their randomisation.

INX, innovator infliximab; RA, rheumatoid arthritis.
