

Racial disparity in arthroplasty remains disjointed

I read with interest the article entitled 'Racial disparities in knee and hip total joint arthroplasty: an 18-year analysis of national medicare data' by Singh *et al.*¹ I congratulate the authors for successfully contributing to the increasing literature of racial disparity in total joint arthroplasty (TJA) research by analysing trends over an 18-year period and including both usage and outcomes. The persistently reduced standardised utilisation rates among black patients for both primary and revision total knee (TKA) and total hip arthroplasty (THA) procedures throughout the entire duration of the study are concerning; however, it is even more alarming that a magnitude increase in disparity occurred for primary TKA usage from 1991 to 2008.

A limitation acknowledged by the authors in using US Medicare Provider Analysis and Review (MedPAR) data is the prevention to evaluate use disparities among racial groups in patients aged <65 years. Interestingly, although Chen *et al.*² also noted a lower total probability of THA and TKA among black patients compared with white patients using the National Inpatient Sample data from 2002 to 2007, there was a higher probability of black patients having THA and TKA compared with white patients among the age groups of 45–54 years and 55–64 years, whereas the reverse was seen in the age groups of 65–74 years and 75–84 years. Understanding this age-related variance may provide insight into addressing racial disparities in the >65-year-old cohort.

Although identification of disparities in receipt of revision arthroplasty between racial groups is known, defining the key level (system, provider or patient) at which to counteract such disparity is more elusive. Hausmann *et al.*³ showed that the rates of recommendation for TJA were less in black patients compared with whites among Veteran Affairs orthopaedic clinics but this difference was not significant after adjusting for surveyed patient preference for TJA. After adjusting for additional factors, several studies corroborate patient preference and willingness to undergo a procedure as a major influence in receipt of arthroplasty.^{4–7} The Department of Health and Human Services (HHS) recently outlined an action plan to reduce racial and ethnic disparities.⁸ However, this was largely focused on healthcare coverage and access as well as HHS efficiency and transparency. While system level changes are being evaluated, more focused and coordinated efforts are needed at the provider and patient level. Persistent disparity within a Medicare population, as shown by Singh *et al.*,¹ provides further evidence

that healthcare coverage is not the leading barrier to arthroplasty. Patients, themselves, are key stakeholders and we must engage and employ them to be involved in the process of identifying areas that providers can address and correct to bridge the disparity gap. Understanding how to appropriately recognise ethnic variation in preferences and perception of benefit are skills that providers must learn to combat this growing inequality. Funding for research and education in this area is requisite from orthopaedic, rheumatology and primary care professional organisations.
