ABSTRACT

Objectives To investigate how the genetic susceptibility gene DIO2 confers risk to osteoarthritis (OA) onset in humans and to explore whether counteracting the deleterious effect could contribute to novel therapeutic approaches.

Methods Epigenetically regulated expression of DIO2 was explored by assessing methylation of positional CpG-dinucleotides and the respective DIO2 expression in OA-affected and macroscopically preserved articular cartilage from end-stage OA patients. In a human in vitro chondrogenesis model, we measured the effects when thyroid signalling during culturing was either enhanced (excess T3 or lentiviral induced DIO2 overexpression) or decreased (iodoacetic acid).

Results OA-related changes in methylation at a specific CpG dinucleotide upstream of DIO2 caused significant upregulation of its expression (β=4.96; p=0.0016). This effect was enhanced and appeared driven specifically by DIO2 rs225014 risk allele carriers (β=5.58, p=0.0006). During in vitro chondrogenesis, DIO2 overexpression resulted in a significant reduced capacity of chondrocytes to deposit extracellular matrix (ECM) components, concurrent with significant induction of ECM degrading enzymes (ADAMTS5, MMP13) and markers of mineralisation (ALPL, COL1A1). Given their concurrent and significant upregulation of expression, this process is likely mediated via HIF-2α/RUNX2 signalling. In contrast, we showed that inhibiting deiodinases during in vitro chondrogenesis contributed to prolonged cartilage homeostasis as reflected by significant increased deposition of ECM components and attenuated upregulation of matrix degrading enzymes.

Conclusions Our findings show how genetic variation at DIO2 could confer risk to OA and raised the possibility that counteracting thyroid signalling may be a novel therapeutic approach.

INTRODUCTION

Osteoarthritis (OA) is a prevalent, complex, disabling disease of articular joints, characterised by degradation of articular cartilage and remodelling of the subchondral bone. There is no effective therapy to reverse or slow down the disease except for joint replacement surgery at the end stage. As a result, OA has a large detrimental impact on the quality of life of the elderly and causes a major burden on health and social care.1 To allow development of new therapies, there is an ongoing need for insight into the underlying mechanisms driving OA. Genetic studies provided evidence that genes orchestrating growth plate endochondral ossification play a underlying role in common OA susceptibility,2 hence functional follow-up approaches require focus on both the early developmental and late-acting effects of these OA genes. A notable example is the deiodinase iodothyronine type 2 (D2) gene (DIO2) with the C-allele of the single nucleotide polymorphism (SNP) rs225014 (frequency ~ 0.35) located in the coding region that conferred consistent risk to OA.3,4 The gene product of DIO2 is responsible for catalysing the conversion of intracellular inactive thyroid hormone (T4) to active thyroid hormone (T3). T3 subsequently signals terminal maturation of growth plate chondrocytes leading to cell hypertrophy, cartilage matrix destruction mediated via upregulation of hypoxia inducible factor-2α (HIF-2α) and runt-related transcription factor-2 (RUNX2),5,6 mineralisation of the cartilage and eventually formation of bone.7 There are striking parallels between the chondrocyte signalling events that take place in the growth plate and those of hypertrophic chondrocytes in OA-affected articular cartilage.8 This has led to the hypothesis that with age and environmental stresses the propensity of the highly specialised, maturational arrested articular chondrocytes is affected by loss of epigenic control. Progression of age and disease could result in reactivation of genes involved in endochondral ossification, leading to loss and mineralisation of articular cartilage, a process known to contribute to OA.9–10 Functional genomic studies showed high expression of DIO2 mRNA and D2 protein levels in osteoarthritic as compared with healthy cartilage.5 Further, DIO2 allelic imbalance was assessed and showed that the OA risk allele ‘C’ was more abundantly present in articular joint tissues than the wildtype allele ‘T’.11 In transgenic rats, DIO2 overexpression conferred risk to articular cartilage destruction.12 The underlying mechanism how the DIO2 SNP confers susceptibility to OA in humans remains, however, to be
determined,\textsuperscript{14} but most likely acts via aberrant upregulation of its expression. The DIO2 locus in humans contains several putative CCCTC-binding factor (CTCF) binding sites, including one that is overlapping with the rs225014 location.\textsuperscript{15} CTCF is considered to facilitate long-range chromatin interactions in order to insulate gene expression, and distal transcriptional elements on the genome are brought in close proximity to transcriptional start sites (TSSs) of genes to inhibit expression.\textsuperscript{16}

In the current study, we focus on regulatory mechanisms of DIO2 expression in preserved and osteoarthritic human articular cartilage, thereby taking into account the DIO2 risk allele. The direct effect of changes in DIO2 expression on chondrocyte function and human cartilage extracellular matrix (ECM) homeostasis is subsequently studied in human in vitro chondrogenesis models, which should be considered a well-defined system for studying changes in the ECM when chondrocytes differentiate, become hypertrophic and start to exhibit cartilage-debilitating expression patterns.

**MATERIALS AND METHODS**

The ongoing RAAK study is aimed at the biobanking of joint materials (cartilage, bone and, where available, ligaments) and mesenchymal stem cells and primary chondrocytes of patients in the Leiden University Medical Center. In the current study, we used paired preserved and OA-affected cartilage samples from 52 Caucasian end-stage OA patients undergoing joint replacement surgery for primary OA (23 hips, 29 knees). For additional details on the RAAK study, cell cultures, RNA and DNA extraction, quantitative RT-PCR, ChIP and the data analysis, see online supplemental methods.

**Electrophoretic mobility shift assay**

For electrophoretic mobility shift assays (EMSAs), synthetic oligonucleotides containing the putative CTCF binding site were 5′-end labelled by γ-\textsuperscript{32}P-ATP and subsequently purified by gel filtration on Sephadex G-25 Medium columns. For additional details, see online supplemental methods.

**Quantification of methylation**

The methylated fraction of CpG dinucleotides was assessed with MALDI-TOF mass spectrometry (Epityper, Sequenom), a commonly applied method to quantify CpG methylation.\textsuperscript{17–19} For additional details, see online supplemental methods.

**Lentiviral constructs and transduction**

C-terminal FLAG-tagged cys-D2 (kindly provided by Prof. Dr. Bianco\textsuperscript{20}) was digested with EcoRI followed by Klenow treatment and digestion with XbaI. Inserts were inserted into the EcoRV-XbaI sites of the pLV-CMV-IRES-eGFP Lentiviral backbone. For additional details, see online supplemental methods.

**In vitro chondrogenesis**

3D pellets were formed using 2.5×10^5 human bone marrow-derived mesenchymal stem cells (hBMSCs). Chondrogenesis was initiated in serum-free chondrogenic differentiation medium. From day 14 onwards, cell pellets were maintained either in the standard chondrogenic differentiation medium or in the presence of T_3 (10 nM) or IOP (10 μM). For additional details, see online supplemental methods.

**Relative pixel intensity**

The relative pixel intensity was computed by loading the photos into ImageJ (V1.47).\textsuperscript{21–23} For additional details, see online supplemental methods.

**RESULTS**

**Epigenetic regulation of DIO2 expression by CpG methylation in articular cartilage**

Online available ChIP-seq data revealed multiple transcription factors to bind the rs225014 locus of which CTCF was predicted to bind with the highest certainty (see online supplementary figure S1). To assess the regulatory properties of the CTCF binding site overlapping rs225014 and to test whether the rs225014 alleles directly affect the binding, we performed an EMSA. The putative CTCF sequence overlapping rs225014 (DIO2-CTCF1) was found not functional nor, for that matter, dependent of the rs225014 alleles (see online supplementary figure S2, lanes 1–6).

As no further TFs were confidently predicted to bind the rs225014 locus, we set out to elucidate putative regulatory mechanisms of DIO2, independent of the rs225014 base change. We, therefore, quantified expression of DIO2 and methylation of 23 CpG dinucleotides across the DIO2 locus in macroscopically preserved and OA-affected cartilage from joints of patients undergoing total arthroplasty of the knee (N=29) or hip (N=23) (RAAK study; see online supplementary table S1). We found borderline significant upregulation of DIO2 expression (β=0.22, p=0.063, figure 1C) in OA compared with preserved cartilage. Furthermore, we observed several CpG dinucleotides to be differentially methylated between preserved and OA-affected cartilage (see online supplementary table S2). However, only for the CpG site 2031 base pairs upstream of the DIO2 transcription start site (CpG-2031, figure 1A) we observed significant differential methylation between OA and preserved cartilage (β=0.028, p=0.0007, figure 1B) and a significant positive association between methylation and DIO2 expression in all samples (β=4.959, p=0.0016, figure 1D; see online supplementary table S2). To confirm the regulatory properties of CpG-2031 on DIO2 expression, we applied 5-aza-2′-deoxycytidine (AZA), a demethylating agent, to the culture medium in eight primary chondrocyte cultures derived from preserved cartilage of total hip replacement patients. Addition resulted in a decrease in methylation at CpG-2031 (p=0.003, figure 2A) corresponding to downregulation of DIO2 expression (p=0.004, figure 2B). Having observed the association between DIO2 expression and OA-associated methylation at CpG-2031, we applied a multivariate model to assess the individual effects of CpG-2031 methylation, joint site, sex, BMI and age and rs225014 alleles on DIO2 expression in articular cartilage (see online supplementary table S3). We could hereby ratify the association between increased CpG-2031 methylation and DIO2 expression (β=4.808, p=0.019).

The most notable observation, however, was the significant independent association of rs225014 genotype on DIO2 expression (β=0.537, p=0.0003), indicating additive effects of both genotype and DNA methylation differences on DIO2 expression. This effect appeared to be mainly driven by the risk allele. Upon stratification by the rs225014 alleles, no significant differences were observed between preserved and OA-affected cartilage among homozygous carriers of the rs225014 wildtype allele T in methylation (β=0.018, p=0.112, figure 1E) or expression (β=−0.017, p=0.929, figure 1F). In carriers of the risk allele, however, an increase was observed in OA cartilage compared with the preserved tissue, both in the difference of CpG-2031 methylation (β=0.034, p=0.00002, figure 1H) and in expression (β=0.35, p=0.012, figure 1I), concomitant with an

increased association between methylation and expression (β=6.816, p=0.00001, figure 1J). As expected, this association between expression and methylation was much smaller among homozygous wildtype allele carriers (β=3.863, p=0.050, figure 1G).

**DIO2 effects on in vitro chondrogenesis; DIO2 overexpression**

To assess the direct effect of DIO2 upregulation upon cartilage matrix homeostasis, we examined in vitro chondrogenesis of hBMSCs in a pellet culture for five consecutive weeks and generated lentiviral-mediated overexpression of DIO2 (figure 3A and online supplementary figure S3). As a result, we observed a greatly reduced expression of genes encoding the main proteins of articular cartilage ECM, COL2A1, ACAN and COL10A1 by reverse transcriptase qPCR (p<0.0001; figure 3A). In parallel, we observed profound and significant upregulated gene expression of the OA markers of hypertrophy and ECM breakdown ADAMTS5, MMP13, RUNX2 and EPAS1 (encoding HIF-2α) from 3 weeks onwards (p<0.05, figure 3A). Histology confirmed a reduced deposition of glycosaminoglycans (GAGs) (figure 3B,C). Although we did not have data to apply proper statistics to produce a significant number, pixel intensity measurements of the pictures reproduced as in figure 3B,C showed us a 35% difference after 35 days between control and DIO2 overexpressing pellets, concurrent with visual lower collagen type II (COL2) and collagen type X (COL10) protein expression by immunohistochemical staining at consecutive weeks compared with controls (figure 3D–G).

**DIO2 effects on in vitro chondrogenesis; thyroid hormone signalling**

To explore whether the effects of DIO2 overexpression are due to enhanced thyroid signalling, we examined in vitro chondrogenesis of hBMSCs from five different donors (see online supplementary table S4) in pellet cultures for seven consecutive weeks (see online supplementary figure S4) while adding active T3 to the chondrogenic medium from two weeks onwards (figure 4A–F). Excess T3 resulted in a significant, progressive reduction in pellet sizes compared with controls, at consecutive weeks of culturing (p<0.05, figure 4G). Respective expression analyses showed a reduced expression of the ECM genes ACAN and COL2A1 (figure 4J), although the downregulation of COL2A1 appeared not statistically significant. Assessing the chondrogenic potential by measuring the ratio between COL2A1 and COL1A1 expression showed a dramatic effect on the chondrogenic effect of the cell system upon addition of T3 (figure 4I). Moreover, the OA markers of hypertrophy and ECM breakdown genes ADAMTS5, RUNX2 and EPAS1 were consistently upregulated from 3 weeks of treatment onwards across the donor cultures (p<0.05, figure 4J). The differences in mean expression of MMP13 between controls and T3-treated cells across the donors at consecutive time points were not significant. Immunohistochemical studies contributed to the confirmation that excess T3 resulted in a reduced expression of COL2 (figure 4C,D) and COL10 (figure 4E,F) and a pronounced reduction of GAGs (figure 4A,B) as reflected by the reduced Alcian blue staining at consecutive time points with an overall mean decrease of 35% (p=0.0002) as measured by the quantitative pixel intensities (figure 4H).

**Pharmacological inhibition of D2**

To investigate whether thyroid signalling blockade attenuates the detrimental effect on cartilage matrix homeostasis, pellet cultures were treated with the pharmacological deiodinase inhibitor iopanoic acid (IOP) during in vitro chondrogenesis of hBMSCs of the five donors. Quantification of surface areas indicated increasing sizes at consecutive time points in the IOP-treated pellets comparable to non-treated, control pellets (figure 5G). Respective expression analyses showed a significantly increased expression of the ECM genes ACAN, COL2A1 and COL10A1 after 3 weeks of treatment (p<0.01, figure 5J), whereas the OA markers of hypertrophy and ECM breakdown genes ADAMTS5, RUNX2 and EPAS1 were similar to control cultures (figure 5J). Furthermore, we found no significant difference in chondrogenic potential between control and IOP-treated pellets when assessing the ratio between COL2A1 and COL1A1 expression (figure 5I). Following these expression patterns, histological analysis of matrix components showed slightly higher levels of COL2 and COL10 staining (figure 5C–F) and higher levels of GAGs as reflected by a significant 4% increase in Alcian blue staining at week 5 of treatment (p=0.018; figure 5A,B and H). Of note is the denser cartilage matrix structure with less cellular lacunae at week 5 of treatment in cells treated with IOP compared with controls (figure 5A). By discriminating ‘cartilage’ from the ‘lacunae’ using the ImageJ data, we could show that administration of IOP resulted in a 10.92% decrease of lacunae (p=4.27×10⁻⁵) on day 35 of treatment.

DISCUSSION

In the current study, we provided insights into how genetic variation at the DIO2 locus confers risk to OA. As a result of OA-related changes in articular cartilage, loss of epigenetic silencing results in upregulation of DIO2 expression among DIO2 rs225014 risk allele carriers (Figures 1 and 2). By applying an in vitro chondrogenesis model with genetically modified hBMSC, we subsequently showed that genetic upregulation of DIO2 expression resulted in a marked reduction of the capacity of chondrocytes to deposit ECM components, concurrent with induction of OA-specific markers of cartilage matrix degeneration (ADAMTS5 and MMP13) and mineralisation (ALPL) (Figure 3).

Given their concurrent upregulation, this process is likely mediated via HIF-2α/Runx2 signalling, a hallmark of the OA disease process. Moreover, we show that the detrimental effects of DIO2 upregulation are a result of increased T3 active, which is likely mediated via D2 action as the conversion of inactive T4 to active T3 by D2 would lead to increased T3 levels. Despite the beneficial effects of IOP on other joint tissues (eg, ligament and synovium) requiring investigation. In this respect, expression of DIO1, being important mainly in the circulation, is likely absent in cartilage tissues. Furthermore, the effect of, for example, IOP on other joint tissues (eg, ligament and synovium) requires investigation. It should be noted that IOP is a general inhibitor of deiodinases and as such could have also inhibited D1 and D3 action. In this respect, expression of DIO1, being important mainly in the circulation, is likely absent in cartilage tissues. Furthermore, by inhibiting D3, we prevented the conversion of active T3 to inactive T4, thereby ruling out the effect of T3 depletion due to inactive D2. Despite the beneficial effects of IOP we observed upregulation of COL10 similar to control cultures reflecting the normal initiation of chondrocyte hypertrophy (Figure 3). Vice versa, we showed that upon addition of T3 chondrocytes directly enter the terminal maturational process towards bone, as reflected by the upregulation of enzymatic breakdown (ADAMTS5) and mineralisation (ALPL, COL1A1), this without significant induction of COL10 deposition (Figure 4E,F). Together, these data indicate that chondrocyte hypertrophy in our model was not necessarily detrimental to cartilage by virtue of attenuated upregulation of matrix degrading enzymes, a constant COL2A1/COL1A1 ratio, denser cartilage matrix structure with significant less cellular lacunae, which indicates a reduced propensity of chondrocytes to enter the terminal maturational process (Figure 5).

Figure 3. Overexpressing DIO2 has a detrimental effect on cartilage extracellular matrix homeostasis. (A) qRT-PCR analysis of DIO2, COL2A1, ACAN, COL10A1, RUNX2, EPAS1, MMP13, ADAMTS5 and ALPL at 21 and 35 days of treatment in the chondrogenic human bone marrow-derived stem cells (hBMSC) transduced with respectively control vector (eGFP) and DIO2 (DIO2_eGFP; see online supplementary figure S3). (B-G) Sections comparing control (top) and DIO2 overexpressing (bottom) chondrogenic hBMSC pellets at 21 and 35 days of treatment. (B, C) Alcian blue staining. (D, E) Immunohistochemical staining of collagen type II. (F, G) Immunohistochemical staining of collagen type X. Scale bar, 100 μm. The expression levels were arbitrarily defined as ‘1’ in the pellets grown under control conditions (white), and data from the pellets overexpressing DIO2 (black) are given as mean±SEM. *p<0.05, **p<0.01, ***p<0.001. SEM<0.05 are not distinguishable in the figure.
homeostasis in contrast to DIO2 upregulation. Our data, therefore, indicate that upregulation of DIO2 does not affect the 'early' hypertrophic expression of COL10A1 but induces the later 'progression stage' marker MMP13, and the 'late stage' markers ALPL and COL1A1.28 In our model, we used the expression of EPAS1 and RUNX2 to show downstream effects of upregulation of DIO2 and observed a significant positive association between T3 and EPAS1. Although such an observation based on association does not imply a direct causal relationship, recent data of Chatonnet et al.29 showed, in a ChIP-seq analysis in mouse C17.2 neural progenitor cells, that EPAS1 harbours specific thyroid hormone nuclear receptor (THR) binding sites and is directly reactive to thyroid hormone. In view of these data, we advocate that active thyroid hormone, likely by local DIO2 action, could have an important impact on EPAS1 upregulation during the pathophysiology of OA.

Figure 4  Thyroid hormone is believed to be a key regulator in human cartilage development. (A–F) Sections of a representative donor (see online supplementary figure S4) comparing control (top) and T3-treated (bottom) chondrogenic human bone marrow-derived stem cell (hBMSC) pellets at 7, 21 and 35 days of treatment. (A, B) Alcian blue staining. (C, D) Immunohistochemical staining of collagen type II. (E, F) Immunohistochemical staining of collagen type X. (A, C and E) Scale bar, 400 μm. (B, D and F) Scale bar, 100 μm. (G) Mean surface area measurements at 7, 21 and 35 days of treatment with N=3 donors in each group. (H) Mean quantitative pixel-intensity measurements (see online supplementary figure S5) at 7, 21 and 35 days of treatment with N=5 donors in each group. (I) Log2 ratio of COL2A1 and COL1A1 with N=5 donors in each group. (J) Mean real-time qRT-PCR analysis of COL2A1, ACAN, COL10A1, COL1A1, ALPL, ADAMTS5, MMP13, RUNX2 and EPAS1 at 7, 21 and 35 days of treatment in chondrogenic hBMSCs of N=5 donors in each group. The surface area measurement, pixel intensities and level of expression were arbitrarily defined as '1' in the pellets grown under control conditions (white) and the data from the pellets grown in the addition of excess T3 (black) are given as mean±SEM. *p<0.05, **p<0.01, ***p<0.001. SEM<0.05 are not distinguishable in the figure.

Additional studies are, however, necessary to elucidate whether T3 is directly affecting expression of \( \text{EPAS1} \) or \( \text{RUNX2} \) for that matter, by binding to a positional thyroid receptor in humans.

Despite the fact that the direction of gene expression changes of \( \text{COL2A1} \) and \( \text{MMP13} \) upon addition of T3 to the culture media appeared consistent with our overall results (figure 4J), the mean differences in expression were not statistically significant across the donors. Most likely this was the result of the considerable heterogeneity in the differential gene expression patterns of these specific genes across donors, especially with respect to timing the respective downregulation and upregulation at consecutive time points (see online supplementary figure S4), a phenomenon generally recognised in the in vitro chondrogenesis models of primary hBMSCs.

We detected several CpG dinucleotides across the \( \text{DIO2} \) locus that were differentially methylated between preserved and
OA-affected cartilage. Although we have only verified their functionality with respect to DIO2 expression, we cannot exclude that methylation at these sites regulates expression of more distal genes. We found a consistent positive correlation between methylation at CpG-2031 and DIO2 expression in articular cartilage among carriers of the rs225014 risk allele, which may not comply with the conventional inverse relation between CpG methylation and gene expression. However, in recent genome-wide approaches, it has been recognised that this conventional relation primarily holds among CpG dinucleotides residing in CpG islands and proximal promoters, whereas gene body and distal enhancer methylation, as is the case for CpG-2031, has been shown to correlate in either direction with gene expression. With respect to our observations of DIO2 expression in preserved and osteoarthritic cartilage, it should be noted that, in contrast to previously reported high upregulation of DIO2 expression in osteoarthritic compared with healthy cartilage,1 we showed a moderate upregulation in osteoarthritic compared with preserved cartilage of the same joint only among carriers of the rs225014 risk allele (figure 1D). This difference suggests that upregulation of DIO2 expression may be an early event in OA pathophysiology and might be set to continue progressively among rs225014 risk allele carriers. We were unable to validate the functionality of a putative CTCF binding site directly at the rs225014 locus nor for that matter the causality of the previously assessed consistent allelic imbalance.11 Possibly, the rs225014 SNP affects three-dimensional chromatin conformations underlying the relation between the rs225014 tagged allelic imbalance and methylation-dependent upregulation of DIO2 among rs225014 risk allele carriers. In conclusion, our data provide evidence in humans that genetic predisposition combined with early OA-related changes results in loss of epigenetic silencing of DIO2, which likely induces EPAS1 and RUNX2 mediated upregulation of cartilage matrix degrading enzymes (ADAMTS5 and MMP13) and mineralisation of matrix (ALPL and COL1A1), thereby driving the OA process most distinctly among DIO2 risk allele carriers. Furthermore, our data show that counteracting the thyroid signalling by inhibiting deiodinases could contribute to needed novel therapeutic approaches of OA.
