ABSTRACT

Background Current recommendations for the management of axial spondyloarthritis (SpA) and psoriatic arthritis are to monitor disease activity and adjust therapy accordingly. However, treatment targets and timetables of change have not been defined. An international expert panel has been convened to develop ‘treat-to-target’ recommendations, based on published evidence and expert opinion.

Objective To review evidence on targeted treatment for axial and peripheral SpA, as well as for psoriatic skin disease.

Methods We performed a systematic literature search covering Medline, Embase and Cochrane, conference abstracts and studies in http://www.clinicaltrials.gov. Results Randomised comparisons of targeted versus routine treatment are lacking. Some studies implemented treatment targets before escalating therapy: in ankylosing spondylitis, most trials used a decrease in Bath Ankylosing Spondylitis Disease Activity Index; in psoriatic arthritis, protocols primarily considered a reduction in swollen and tender joints; in psoriasis, the Modified Psoriasis Severity Score and the Psoriasis Area and Severity Index were used. Complementary evidence correlating these factors with function and radiographic damage at follow-up is sparse and equivocal.

Conclusions There is a need for randomised trials that investigate the value of treat-to-target recommendations in SpA and psoriasis. Several trials have used thresholds of disease activity measures to guide treatment decisions. However, evidence on the effect of these data on long-term outcome is scarce. The search data informed the expert committee regarding the formulation of recommendations and a research agenda.

INTRODUCTION

Recommendations from the Ankylosing Spondylitis Assessment Study (ASAS)/European League Against Rheumatism (EULAR) for the management of ankylosing spondylitis (AS)1 and from EULAR for the management of psoriatic arthritis (PsA)2 are to monitor the disease,1,2 adjust treatment appropriately,2 and adapt the frequency of monitoring depending on the course and severity of the disease.2 However, no evidence that a guided treatment strategy is as effective for AS and PsA as it is for rheumatoid arthritis (RA)3 has yet been established. This is partly due to the heterogeneity of the presentations of these and related diseases, which some would group under the broader term, spondyloarthritis (SpA). In fact, it has been suggested that the terms axial SpA and peripheral SpA could be considered rather than the traditional names.4 To address this issue, an international panel of expert rheumatologists and patients convened to discuss recommendations on a ‘treat-to-target’ (T2T) concept for SpA. In line with respective recommendations by EULAR,5 a systematic literature review of the current state of evidence was deemed necessary. In the following, we present this systematic literature review, which served as the background for generating the recommendations document.6

METHODS

We performed a systematic literature search of the Medline, Embase and Cochrane databases. This search was based on a PICO (population, intervention, control and outcome) strategy and search terms developed in the course of discussions of the task force’s steering committee. Box 1 shows the PICO strategy, and online supplementary table S1 lists the search terms.

We retrieved publications from each database’s inception to September 2011. We also screened 2010 and 2011 EULAR and American College of Rheumatology (ACR) conference abstracts7,8 and accessed the US National Institutes of Health (NIH) database on clinical trials.9 We selected eligible studies according to our inclusion criteria (see box 1 and online supplementary table S1) and compiled the applied measures of disease activity and the thresholds and timelines that guided the decision to change therapy in the respective study protocols. The primary aim of the search was retrieval of strategic studies that compared a therapy steered towards a prespecified treatment

target versus a conventional, non-steered approach, as is available for RA.10 Secondly, we reviewed ancillary literature providing circumstantial evidence that a steered therapy might be beneficial during long-term follow-up.

RESULTS
We initially retrieved 1976 publications in Medline and Embase, and 1002 in Cochrane. By title and abstract screening, we selected 159 of these for full-text review, and finally included 21 papers plus one additional publication found by hand-search. Of these, 12 trials enrolled patients with AS, five included patients with PsA, and two studies included both AS and PsA patients (table 1). No studies on peripheral SpA were obtained; three studies addressed patients with psoriasis. No conference abstracts and no trials from the NIH database provided data on treatment targets. Figure 1 illustrates the search and selection process.

The most important result of the search was the failure to find any randomised comparison evaluating a T2T approach versus routine treatment. However, several publications report on targets and timelines that were used as thresholds before escalating therapy.

Axial SpA (including AS and non-radiographic axial SpA)
Overall, we found 14 studies11–24 with predetermined treatment targets in AS that were suitable for inclusion. Table 1 specifies the measures of disease activity or function and timelines as well as cut-off points used as indication of (in)sufficient response. The baseline characteristics of the study populations were comparable with regard to inclusion criteria, disease activity, function, age and disease duration (online supplementary table S2 lists details of the included studies and baseline characteristics of the patients).

Definitions of treatment targets and timelines
The majority of studies used the Bath AS Disease Activity Index (BASDAI) at follow-up for treatment ‘escalation’ until a prespecified outcome was achieved.12 15 17 18 This outcome was defined as BASDAI<3 at two consecutive assessments starting from weeks 30 and 36 in one trial,12 while in most studies, a percentage reduction from baseline was required, being either ≥20% after 12 weeks,17 ≥40% after 14 weeks18 or ≥50% after 6 months.15 17 Two protocols required a decline of ≥20%11 or ≥40%14 in the response criteria of the ASAS after 12 weeks.

One study18 based treatment decisions on the erythrocyte sedimentation rate (ESR) at follow-up and required a ≥1 mm reduction per week. One trial that included AS and PsA patients18 required a ≥40% reduction in patient global assessment of disease activity (PGA) after 14 weeks, otherwise infliximab (IFX) frequency was increased from an 8-weekly to a 4-weekly schedule (table 1).

Several authors used combined targets, mostly combinations of the BASDAI19 22 or the Bath AS Metrology Index (BASMi)24 with either acute phase reactants19 22 or the physician global assessment (PhysGA).24 Meric et al16 measured serum IFX levels after four infusions to customise infusion schedules previously determined according to the BASDAI. Reductions in morning stiffness and pain were used to adjust golimumab therapy13 and—expanded by the ESR—also to guide dose escalations of mazelanizal.20 Cheung et al22 reported therapeutic outcomes using Australian Pharmaceutical Benefit Schedule standards, which only reinforce ‘continuation’ of IFX after decline of BASDAI by ≥2 points and ≥20% improvement in ESR and/or C-reactive protein (CRP) (table 1). Several studies tested the efficacy of ‘on-demand’ treatment in the case of relapse after cessation of IFX.23 24 The definition of relapse was based on a short questionnaire in combination with BASDAI and an increase in acute phase reactants (table 1).15 or an absolute BASMI or PhysGA of ≥4.24 Therapy was tapered according to ESR23 BASDAI and serum IFX levels16 (table 1).

In AS, prospective analyses to identify the predictive value of the above measures for long-term functional and radiographic outcomes have not been carried out.

Psoriatic arthritis
Seven studies fulfilled our inclusion criteria for PsA.18 19 23–29 Table 1 details their treatment targets. Online supplementary table S2 shows study details and patients’ baseline characteristics.

In the majority, the treatment target was a reduction in swollen and tender joint counts.26–29 The prespecified decrease for a treatment to be considered sufficiently effective was a reduction in joint counts of ≥10% after 16 weeks,26 ≥20% after 38 and 46 weeks,27 29 ≥50% after 14 weeks28 or ≥40% after 3 months.29 Two trials18 19 included mixed SpA populations and used ≥40% reduction in PGA after 14 weeks,18 or ESR and CRP19 (table 1). Some prospective studies investigated the correlation between clinical symptoms and progression of radiographic damage and reported a predictive capacity of synovitis,30–32 dactylitis33 and CRP14, while other authors did not observe these associations.15 Serological markers that can predict long-term outcome in PsA are under investigation.36

There were no trials available that specifically investigated targeted treatment in other peripheral SpAs or contributed evidence on correlation with long-term outcomes.
We present a systematic review of targeted treatment for SpA and psoriasis that informed the consensus-finding process of the expert committee for T2T-SpA recommendations.

Randomised trials designed to compare targeted treatment with another type of care are not available, but evidence can be derived from studies that apply target-oriented treatment adaptation. The majority of designs suggest use of the BASDAI to evaluate therapeutic response in AS (but other composite measures such as ASDAS\textsuperscript{41,42} seem to be increasingly used), swollen and tender joint counts for PsA, and MPSS and PASI for psoriasis. In many studies, response was evaluated after 12–14 weeks, for example, to pause etanercept as soon as a target of PGA of ≤2 (clear, almost clear or mild) was reached.\textsuperscript{40}
while others stretched out to 36 weeks. Importantly, no information on long-term outcomes is available. Composite measures of disease activity have not yet been formally evaluated for PsA. Likewise, no such studies are available for other peripheral spondyloarthritides including reactive arthritis. Some trials for reactive arthritis used antibiotic therapy (reviewed by Hannu⁴³). These studies are not included here because they did not use criteria for insufficient response.

The definition of pertinent treatment targets for SpA is challenging because of the heterogeneity of the disease, including axial, peripheral and extra-articular/extraspinal manifestations. Moreover, no data on a positive effect on physical function and radiographic damage resulting from a T2T strategy have been published for SpA.

The data presented informed the task force on the current state of evidence and clearly reveal that further research is needed. In particular, clinical trials comparing the value of treatment steered by levels of disease activity versus conventional therapy in SpA, both axial and peripheral, are needed.
