Accepted 26 July 2004

Background: Hypoandrogenicity is common in obesity and in chronic inflammatory diseases such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Adrenal androgens such as androstenedione (ASD) and dehydroepiandrosterone (DHEA) sulphate are low, which partly depends on the influence of TNF in chronic inflammatory diseases. Leptin is stimulated by TNF and is associated with hypoandrogenicity in non-inflammatory conditions.

Objective: To study the interrelation between serum levels of leptin and adrenal steroids in SLE and RA.

Methods: In a retrospective study, serum levels of leptin, ASD, DHEA, and 17-hydroxyprogesterone (17OHP) were measured by ELISA, and serum levels of cortisol by radioimmunoassay in 30 patients with RA, 32 with SLE, and 54 healthy control subjects (HS).

Results: In SLE and RA but not HS, serum levels of ASD correlated negatively with serum levels of leptin ($p < 0.01$) independently of prior prednisolone treatment in patients with SLE ($p = 0.013$) and tended to be independent of prednisolone in patients with RA ($p = 0.067$). In a partial correlation analysis, this interrelation remained significant after controlling for daily prednisolone dose in both patient groups. In both patient groups, serum leptin levels correlated negatively with the molar ratio of serum ASD/serum cortisol and serum ASD/serum 17OHP, and positively with the molar ratio of serum DHEA/serum ASD.

Conclusions: The negative correlation of serum leptin and ASD or, particularly, ASD/17OHP, together with its known anti-androgenic effects indicate that leptin is also involved in hypoandrogenicity in patients with SLE and RA. Leptin may be an important link between chronic inflammation and the hypoandrogenic state.

Chronic inflammatory diseases in humans, such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA), are characterised by a dramatic decrease of serum levels of adrenal androgens.^{1–9} Interestingly, hypoandrogenicity is a very common phenomenon in many chronic inflammatory diseases.^{10–17} In RA and other autoimmune diseases it has been stated that alteration of androgen secretion has an impact on perpetuation of the disease.^{18–19} Treatment with dehydroepiandrosterone (DHEA), as the starting-point of androgen conversion (fig 1), has been proved to be a therapeutic alternative in SLE^{20–22} and, possibly, in patients with chronic inflammatory bowel disease.²³ This indicates that androgens have an anti-inflammatory influence, which is switched off during long term systemic inflammatory responses. This phenomenon is largely disease-unspecific.

Interestingly, a strikingly similar hypoandrogenic state exists in obese people with metabolic syndrome leading to low levels of androstenedione (ASD) and testosterone.^{24–25} Thus, the fat tissue hormone leptin may be an important link between hypoandrogenicity and obesity. Leptin, the product of the *ob* gene,²⁶ is a pleiotropic molecule which was originally described in the leptin deficient *ob/ob* mice. A large number of cell types which can produce this hormone (for example, white adipose tissue cells, but also endothelial cells, T lymphocytes, bone marrow cells, spleen cells, platelets etc).²⁷ Its role for food intake (inhibitory effect) and metabolic and endocrine functions has been extensively described. However, leptin also regulates immunity, inflammation, haematopoiesis,²⁷ and adrenal androgen secretion. Intervention studies with androgens show that correction of relative hypogonadism in men with visceral obesity and other manifestations of the metabolic syndrome decreases the abdominal fat mass and reverses glucose intolerance.²⁸ In the

obese state, the fat tissue hormone leptin was found to have a dominant role for hypoandrogenicity because leptin inhibits gonadal androgen secretion.^{29–31} Furthermore, a recent study in bovine adrenocortical cells demonstrated leptin induced inhibition of 17 α -hydroxylase P450 mRNA expression,³² which is the key enzyme for androgen production (fig 1). The same study demonstrated leptin induced inhibition of P450c21 and P450scc mRNA expression (fig 1). In addition, the same group showed that a similar inhibitory influence of leptin exists on human adrenocortical cells (reviewed by Glasow and Bornstein³³) (fig 1). Thus, leptin may be an important factor for hypoandrogenicity in obese people and also in chronic inflammatory diseases.

This study aimed at investigating serum leptin levels in relation to serum concentration of adrenal androgens in patients with chronic inflammatory diseases. To estimate a possible influential role of leptin at the P450c17 and 3 β -hydroxysteroid dehydrogenase level, the interrelation of serum leptin and several molar steroid hormone ratios was investigated. We focused on patients with SLE and RA in order to demonstrate possible disease-unspecific changes.

METHODS

Healthy subjects and patients

We included 30 white patients with RA fulfilling the American College of Rheumatology criteria for diagnosis.³⁴ Disease activity was assessed by the number of swollen and tender joints and erythrocyte sedimentation rate. Furthermore, we enrolled 32 white patients with SLE

Abbreviations: ASD, androstenedione; DHEA, dehydroepiandrosterone; ELISA, enzyme linked immunosorbent assay; HS, healthy subjects; 17OHP, 17-hydroxyprogesterone; RA, rheumatoid arthritis; SLE, systemic lupus erythematosus; TNF, tumour necrosis factor

Figure 1 Pathways of steroidogenesis. A line with a bar at the end demonstrates that the respective mediator inhibits the enzyme step (tumour necrosis factor (TNF)). Abbreviations: 3βHSD, 3β-hydroxysteroid dehydrogenase; 11βHSD I and II; 11β-hydroxysteroid dehydrogenase types I and II; DHEA, dehydroepiandrosterone; DHEAS, DHEA sulphate; DST, DHEA sulphotransferase; IL6, interleukin 6; P450c11, 11β-hydroxylase; P450c17, 17α-hydroxylase and 17/20-lyase (double enzyme step); P450c21, 21α-hydroxylase; P450scc, side chain cleavage enzyme; ST, DHEAS sulphatase; StAR, steroidogenic acute regulatory protein; TNF, tumour necrosis factor.

according to the criteria of the American College of Rheumatology.³⁵ In the latter patients, clinical activity was assessed by the SLE Disease Activity Index (SLEDAI). Table 1 shows the basic characteristics of both disease groups and their treatment. Clearly, patients in both disease groups presented mild to moderate disease activity. Patients of both disease groups entered the study consecutively between 2000 and 2002. Some of the patients with RA and SLE were the subject of a recent study which dealt with other aspects of these diseases (manuscript submitted).

For comparison, 54 white healthy control subjects (HS) were included (mean (SEM) age 40.8 (1.5) years), and their health status was verified by a 33 item questionnaire, as previously described.³⁶ Fertile women (HS and patients) were not taking contraceptives and they were in the early to mid-follicular phase of the menstrual cycle as estimated by serum progesterone levels (table 1). Information about the HS was

collected between 2000 and 2002 as part of another investigation which dealt with different aspects (see above, manuscript submitted).

Because this was a retrospective study, we did not measure body mass and body height so that comparisons of serum leptin levels between groups were not made. Our intention was to focus only on relations between serum levels of leptin and adrenal steroids within the respective groups. Because we would expect raised leptin levels in subjects with increased body mass index, the mentioned significant correlations may be explained by the subjects' body mass index. We believe that the missing body mass index did not markedly influence our report.

On the day of the visit, between 8 00 and 10 00 am, blood for further determination of leptin and steroid hormones was taken, and serum was stored at -30°C in adequate aliquots. All patients and HS gave written consent for further

Table 1 Basic characteristics of healthy subjects and patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). The patients should not be compared owing to a different mean age of the groups.

investigation of their blood samples. Patients and HS lived in the catchment area of the University Hospital Regensburg, Bavaria.

Laboratory parameters

Radioimmunoassay was used for the quantitative determination of serum levels of cortisol (Coulter Immunotech, Marseilles, France; detection limit 10 nmol/l; cross reactivity with prednisolone ≤6%). Serum levels of ASD (IBL, Hamburg, Germany; detection limit 0.15 nmol/l), 17-hydroxyprogesterone (17OHP; IBL, Hamburg, Germany; detection limit 0.3 nmol/l), and DHEA (Diagnostic Systems Laboratory, Webster, Texas; detection limit 0.13 nmol/l) were measured by immunometric enzyme immunoassays. Serum leptin was measured by an enzyme linked immunosorbent assay (ELISA) with a detection limit of 7.8 pg/ml (R&D Systems, Wiesbaden, Germany). As indicated by the suppliers, intra-assay and interassay coefficients of variation for all assays were below 10%.

To demonstrate a preponderance of one serum hormone over another, the molar ratio of these hormones was calculated (given without unit). This procedure detects a hormonal shift through one to more adrenal enzyme steps which can demonstrate a preponderance of an adrenal pathway (fig 1): ASD/cortisol for P450c21, P450c11, and 17/20-lyase (2nd reaction of the P450c17) into the direction of ASD, ASD/17OHP for the 17/20-lyase (2nd reaction of the P450c17) into the direction of ASD, and DHEA/ASD for the 3β-hydroxysteroid dehydrogenase into the direction of DHEA (fig 1).

Statistical analysis

Investigation of an interrelation between two variables was done using Spearman rank correlation analysis (SPSS/PC for Windows, version 10.0.5, SPSS, Inc, Chicago). Medians within groups were compared by Mann-Whitney signed rank test (SPSS). To control an interrelation between two variables for a third control parameter partial correlation analysis was used (SPSS). Values of $p < 0.05$ were considered to be significant and results are given as mean (SEM).

RESULTS

In patients with SLE and RA, serum levels of ASD correlated negatively with serum leptin concentrations (fig 2) which was similar in the subgroups with and without prior prednisolone treatment (fig 2). In all patients with SLE and RA including those with prior prednisolone treatment, a highly significant interrelation existed (SLE: $R_{\text{Rank}} = -0.618$, $p < 0.0001$, and RA: $R_{\text{Rank}} = -0.601$, $p < 0.0001$, respectively). After controlling this interrelation for daily prednisolone dose this particular negative correlation remained significant (SLE: $R_{\text{partial}} = -0.483$, $p = 0.006$, and RA: $R_{\text{partial}} = -0.439$, $p = 0.028$, respectively). No such correlations were seen in HS (fig 2, lower panel).

To estimate the hormonal preponderance of ASD versus cortisol, the molar ratio of these two hormones was calculated. This ratio correlated negatively with serum leptin levels in all patients, including those with prior prednisolone treatment (fig 3). In patients with SLE, this interrelation remained significant after controlling for daily prednisolone dose ($R_{\text{partial}} = -0.556$, $p = 0.001$). In contrast, in patients with RA controlling for prednisolone intake abolished the negative correlation between serum leptin and this particular ratio ($R_{\text{partial}} = -0.313$, $p = 0.210$). In HS, no such negative correlation was seen (fig 3, lower panel).

To directly investigate the shift from 17-OHP to ASD, the molar ratio of these hormones was calculated (fig 1). In support of above mentioned results, this ratio also correlated negatively with serum leptin levels (fig 4). In addition, both in patients with SLE and RA this negative correlation remained significant after controlling for daily prednisolone dose (SLE: $R_{\text{partial}} = -0.400$, $p = 0.026$; RA: $R_{\text{partial}} = -0.448$, $p = 0.022$). These correlations were not significantly negative in HS (fig 4, lower panel).

These data clearly indicate a reduction of the adrenal androgen ASD in relation to upstream steroid hormones. To estimate the role of the 3β-hydroxysteroid dehydrogenase (fig 1), the molar ratio of DHEA/ASD was calculated (fig 1). Interestingly, this ratio correlated positively with serum leptin levels in all patients with SLE and RA (fig 5). This positive interrelation remained significant in those patients with SLE and RA without prior prednisolone treatment (SLE:

Figure 2 Interrelation between serum levels of ASD and leptin in patients with SLE, RA, and HS. Open symbols (broken line) stand for patients with prior prednisolone treatment whereas black symbols (solid line) represent patients without prior prednisolone treatment. The linear regression lines, the Spearman rank correlation coefficients (R_{Rank}) and the p values are given in the panels. Direct comparison of patients with SLE, RA, and HS is not meaningful because of the unknown body mass index (take notice of the different scales).

$R_{\text{Rank}} = 0.648$, $p = 0.043$; RA: $R_{\text{Rank}} = 0.833$, $p = 0.005$). There was no such correlation in HS (fig 5, lower panel).

Because leptin serum levels were described as higher in women than in men, we compared our readout parameters between women and men within the respective disease groups. Serum leptin levels were higher in women than in men, and this difference was significant in HS and patients with RA (table 2). No differences were found for serum levels of ASD (table 2) and all calculated molar ratios (not shown).

DISCUSSION

This study demonstrates an inverse interrelation between serum levels of leptin and ASD or molar ratios of serum levels of ASD/cortisol or ASD/17OHP. This was accompanied by a positive correlation between serum leptin and the molar ratio of serum DHEA/serum ASD (fig 1). All these correlations were particularly stable in patients with SLE irrespective of prior prednisolone treatment.

Several recent studies demonstrated the inhibitory influence of leptin on gonadal and adrenocortical ASD production,^{29–31} which is achieved by direct inhibition of the respective P450 enzyme mRNA expression in steroid hormone producing cells.^{32–33} Our studies in chronic inflammatory

diseases corroborate the possibility that leptin may have an inhibitory influence on ASD secretion which was not seen in our HS. In view of the known *in vitro* data of leptin induced inhibition of ASD (reviewed by Glasow and Bornstein³³), our study supports the concept that the important enzyme step of the 17/20-lyase (2nd reaction of the P450c17) is particularly altered in these patients (fig 1). Moreover, owing to the positive correlation between serum leptin and the molar ratio serum DHEA/serum ASD, 3 β -hydroxysteroid dehydrogenase may also be altered by leptin (not in HS). However, this latter fact has not been investigated *in vitro* in adrenocortical cells and, thus, remains to be elucidated. Because we and others believe that androgens are anti-inflammatory in chronic inflammatory diseases, their continuous reduction is unfavourable for the disease outcome. Loss of ASD would lead to a loss of testosterone and dihydrotestosterone (fig 1). The question arises as to the more general role of leptin during an inflammatory episode and why leptin should have a proinflammatory role.

Leptin from adipose tissue is stimulated by proinflammatory cytokines such as TNF and interleukin 1 β which has been demonstrated several times.^{37–41} These cytokines seem to stimulate short term release of stored leptin, although its

Figure 3 Interrelation between the molar ratio of serum ASD/serum cortisol and leptin in all patients with SLE, RA, and HS. In both disease groups, patients with and without prior prednisolone treatment were included. The linear regression line, the Spearman rank correlation coefficient (R_{Rank}) and the p value are given in the panels. Direct comparison of patients with SLE, RA, and HS is not meaningful because of the unknown body mass index (take notice of different scales).

production may even be inhibited during long term in vitro stimulation with TNF.⁴² Thus, the acute cytokine driven rise in leptin may support the initial proinflammatory response. Indeed, human leptin stimulates proliferation and activation of human circulating monocytes through the leptin receptor, which is a member of the interleukin 6 receptor related cytokine receptors.⁴³ Leptin is a fundamental factor for human T cell proliferation and it induces T helper type 1 immune reactions.⁴⁴ Moreover, fat mass in humans is directly related to white blood count, which is closely related to leptin serum levels,⁴⁵ and leptin stimulates oxidative species production by stimulated polymorphonuclear neutrophils.⁴⁶ Thus, leptin may be an “acute phase protein of fat tissue” which supports the immune system during a short term infectious disease. Indeed, leptin deficient mice exhibit impaired host defence in Gram negative pneumonia,⁴⁷ and starvation with low serum leptin levels leads to immunosuppression.⁴⁸ Interestingly, serum leptin levels are increased in survivors of sepsis as compared with non-survivors.⁴⁹ All these factors indicate that leptin has been evolutionarily conserved for an acute inflammatory response. During some chronic inflammatory disease, serum levels of leptin are also increased.^{50–52} In our study we could not confirm this fact

because we did not match for body mass index and age (thus, comparison of the groups is not allowed). As in the acute infectious condition, most probably the proinflammatory load increases serum leptin which depends on fat mass. One may speculate that leptin is a systemic indicator of the available energy resources: it may be necessary for the fine tuning of the vastly energy consuming immune response. In this respect, it supports the proinflammatory pathways of the immune system.

In view of these general immune supportive aspects of leptin, leptin is probably a proinflammatory mediator which was evolutionarily saved for the acute inflammatory episode. In this respect, inhibition of leptin induced androgens is an indication of its proinflammatory role. TNF, like leptin, directly inhibits adrenal steroidogenesis by modulating P450c17 and others.⁵³ In a recent long term study in patients with RA, anti-TNF treatment obviously favoured androgen secretion, which demonstrates the detrimental influence of this cytokine on androgens.⁵⁴ Because both TNF and leptin can inhibit androgen secretion in parallel, one may speculate that the negative correlations between serum leptin and ASD (and ratios) are only to be found in patients with a high proinflammatory load and, thus, did not occur in our HS.

Figure 4 Interrelation between the molar ratio of serum ASD/serum 17OHP and leptin in all patients with SLE, RA, and HS. In both disease groups, patients with and without prior prednisolone treatment were included. The linear regression line, the Spearman rank correlation coefficient (R_{Rank}) and the p value are given in the panels. Direct comparison of patients with SLE, RA, and HS is not meaningful because of the unknown body mass index (take notice of the different scales).

In conclusion, in patients with SLE and RA our study supports the known concept that leptin inhibits androstenedione secretion. In chronic inflammatory diseases, this phenomenon may add to the well known hypoandrogenicity.

Because leptin is a proinflammatory mediator and androgens are anti-inflammatory, preponderance of leptin and hypoandrogenicity may help to perpetuate chronic inflammatory diseases.

Table 2 Basic characteristics of healthy subjects and patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA)

	Women	Men	p Value
Healthy subjects			
Serum leptin (pg/ml)	14490 (2946)	4715 (610)	<0.001
Serum ASD (nmol/l)	13.5 (1.3)	15.6 (1.6)	NS
Systemic lupus erythematosus			
Serum leptin (pg/ml)	11999 (1643)	6319 (2167)	0.064
Serum ASD (nmol/l)	4.6 (0.9)	6.7 (2.0)	NS
Rheumatoid arthritis			
Serum leptin (pg/ml)	3973 (572)	2186 (554)	0.047
Serum ASD (nmol/l)	1.9 (0.3)	3.0 (0.6)	NS

Data are given as means (SEM).
ASD, androstenedione.
The values are not given for comparison of subgroups because body mass index was not available. For this particular leptin assay, the supplier provided mean values for women and men of 20 676 pg/ml (range 3877–77 273) and 4760 pg/ml (2205–11 149), respectively (R&D Systems, Wiesbaden, Germany).

Figure 5 Interrelation between the molar ratio of serum (DHEA)/serum ASD and serum leptin in all patients with SLE, RA, and HS. In both disease groups, patients with and without prior prednisolone treatment were included. The linear regression line, the Spearman rank correlation coefficient (R_{Rank}), and the p value are given in the panels. Direct comparison of patients with SLE, RA, and HS is not meaningful because of the unknown body mass index (take notice of different scales).
