TREATMENT OF OSTEO-ARTHRITIS OF THE KNEES

BY

V. WRIGHT

From the Rheumatism Research Unit, University Department of Medicine, the General Infirmary at Leeds, and the Royal Bath Hospital, Harrogate.

Relatively little has been published about the treatment of osteo-arthritis. Therapy consists mainly of analgesic drugs and local measures such as intra-articular corticosteroids and short-wave diathermy. Few controlled trials have been done and it is difficult to evaluate some reports owing to lack of distinction of response in patients with rheumatoid arthritis and those with osteo-arthritis (Hollander, Brown, Jessar, and Brown, 1958; Duff, 1956; Zuckner, Machek, and Ahern, 1956; Bonner, 1959).

In a study of the value of intra-articular therapy in rheumatic diseases, we have shown that in rheumatoid arthritis intra-articular injections of hydrocortisone acetate and hydrocortisone tertiary butyl acetate produce improvement in pain, tenderness, walking time, range of movement, and limitation of extension (Chandler, Wright, and Hartfall, 1958). In contrast, a trial of these two drugs in osteo-arthritis, conducted under exactly similar conditions, showed only a transient relief of pain (Wright, Chandler, Morison, and Hartfall, 1960). It was noted, moreover, that with 33 per cent. of patients there was improvement from the injection of inert material, and this interesting problem formed the basis of a further study by Morison, Woodmansey, and Young (1961).

The present controlled study was designed therefore to ascertain the relative value of courses of placebo tablets, placebo injections, and short-wave diathermy in the treatment of osteo-arthritis.

Design of Trial

38 patients whose main complaint arose from osteo-arthritis of the knees were included in the trial. In 21 both knees were treated and in seventeen only one knee, giving a total of 59 joints. No patients had received intra-articular therapy or short-wave diathermy within 6 months of the start of the trial. The study was conducted in an out-patient department.

One of three courses of treatment was randomly allocated to each patient from a previously prepared master sheet. Each course lasted 6 weeks.

(1) Those receiving placebo tablets took one tablet twice daily.

(2) Those receiving intra-articular therapy received four fortnightly injections of 2 ml. normal saline into the knees.

(3) Short-wave diathermy was given for 20 minutes three times a week for 6 weeks.

Particulars of the patients in each group are shown in Table I.

Assessments were made immediately before the start of the trial and at fortnightly intervals after a course of treatment for a maximum of 26 weeks from the start of trial. The following measurements were recorded:

- Walking time over 75 yards
- Tenderness: 0 = absent, 1 = slight, 2 = moderate, 3 = wincing, 4 = withdrawal and/or exclamation.
- Pain: 0 = none, 1 = slight on walking, 2 = marked on walking, 3 = mild at rest, 4 = severe at rest.

Number of analgesic tablets taken daily.

Eleven knees improved after a course of placebo injections and this improvement compared with that on placebo tablets is probably significant (P <0.05). There was no significant difference between improvement after short-wave diathermy and that on placebo injections (P <0.01).

More patients showed long-term improvement after short-wave diathermy (11) than after placebo injections (6) and placebo tablets (5), but this difference did not reach the level of significance (P <0.1).

**Discussion**

These findings confirm our previous observations that a proportion of patients with osteo-arthritis will improve after the intra-articular injection of an inert substance or a course of placebo tablets (Wright and others, 1960; Morison and others, 1961). Miller, White, and Norton (1958), in a careful study of the value of intra-articular injections in osteo-arthritis of the knee, investigated 181 patients in five treatment groups receiving different series of five injections at fortnightly intervals:

- (1) Lactic acid and procaine,
- (2) Procaine,
- (3) Physiological saline,
- (4) Hydrocortisone,
- (5) Nothing—a mock injection procedure being carried out.

They found that 84.5 per cent. of the patients in all groups reported subjective improvement 6 weeks after the course, which was confirmed by objective assessment in 84.7 per cent. of the men and 68 per cent. of the women. At 6 months 79.6 per cent. stated that they were improved. The design of their trial precluded assessment of short-term benefit. They obtained a higher percentage of improvement with placebo injections than we experienced, our figures for improvement maintained for more than 6 weeks with injections of physiological saline being 33 per cent. compared with their 80 per cent.

The findings in the present study are more in keeping with the usual incidence of placebo reactors (Lasagna, Mosteller von Felsinger, and Beecher, 1954; Joyce, 1959). The enhanced placebo effect of injections compared with tablets might be anticipated; the aseptic ritual accompanying intra-articular therapy can hardly fail to impress suggestible patients. Miller and others (1958) suggest that, if intra-articular injections for osteo-arthritis are chosen, the least noxious and most economical substance, such as normal saline or nothing (by mock injection), should be used.

The results of the present study indicate that significantly greater benefit was derived from a
The effect of courses of placebo tablets, intra-articular placebo injections, and short-wave diathermy has been studied in 38 patients with osteo-arthritis whose main incapacity arose from involvement of the knees. Courses of treatment were randomly allocated and administered over a period of 6 weeks. Pain, tenderness, walking time, and number of analgesic tablets taken were assessed at the start of the trial and at fortnightly intervals after the course of treatment to a maximum of 6 months. Short-wave diathermy gave significantly better results than placebo tablets, and placebo injections also have greater improvement than placebo tablets (this was significant at the 5 per cent. level).

It is suggested that, of these treatments for osteo-arthritis, short-wave diathermy is preferable as a first choice. If intra-articular therapy is indicated, comparison with previous results suggests that physiological saline is likely to confer as much benefit as hydrocortisone or its analogues.

I am indebted to Prof. S. J. Hartfall, who afforded facilities for this study, to Mr. N. W. Blacow, senior pharmacist, and Miss B. Knowles, physiotherapist, at the General Infirmary, Leeds, for their help, and to Miss B. Thewlis for secretarial assistance.
