Anti-apoptogenic function of TGFβ1 for human synovial cells: TGFβ1 protects cultured synovial cells from mitochondrial perturbation induced by several apoptogenic stimuli

CONCISE REPORT

Objective: To investigate anti-apoptogenic mechanism of transforming growth factor β1 (TGFβ1) towards synovial cells.

Methods: Isolated synovial cells, treated or not with TGFβ1, were cultured in the presence or absence of anti-Fas IgM, proteasome inhibitor Z-Leu-Leu-Leu-aldehyde (LLL-CHO), etoposide, or C2-ceramide. After cultivation, apoptosis of synovial cells was examined by the presence of hypodiploid DNA+ cells, the presence of terminal deoxy (d)-UTP nick end labelling+ cells (TUNEL+ cells), activation of caspasas, and disruption of mitochondrial transmembrane potential (ΔΨm).

Results: Activation of caspase-9 and ΔΨm was found in anti-Fas IgM treated synovial cells. The increment of both hypodiploid DNA+ cells and TUNEL+ cells accompanied by the activation of caspase-8 and caspase-3 was also determined in anti-Fas IgM treated synovial cells. These hallmarks for apoptosis induced by anti-Fas IgM were significantly suppressed in TGFβ1 treated synovial cells. LLL-CHO, etoposide, and C2-ceramide also caused ΔΨm, the increment of both hypodiploid DNA+ cells and TUNEL+ cells, and the activation of both Leu-Glu-His-Asp ase (LEHDase; caspase-9 like activity) and Asp-Glu-Val-Asp ase (DEVDase; caspase-3 like activity) in synovial cells. As determined in anti-Fas IgM treatment, TGFβ1 significantly reduced apoptotic cell death of synovial cells induced by the above chemicals.

Conclusions: The protective effect of TGFβ1 for mitochondrial homeostasis may be important in the anti-apoptogenic function of TGFβ1 for synovial cells.

Cytokines and growth factors present in rheumatoid synovial tissues are important factors which regulate an apoptotic process of synovial cells. Transforming growth factor β1 (TGFβ1) is highly expressed in rheumatoid synovial tissues, and found to possess an anti-apoptogenic effect for synovial cells; this was demonstrated by the experimental results showing that TGFβ1 inhibits Fas mediated apoptosis as well as proteasome inhibitor induced apoptosis in cultured synovial cells. TGFβ1 not only suppresses Fas expression, but increases the expression of Bcl-2 and Bcl-xL in cultured synovial cells. The latter finding implies that TGFβ1 protects synovial cells from apoptotic stimuli through a mitochondria dependent mechanism.

We show in this study that mitochondrial perturbation as well as both DNA fragmentation and the activation of caspases in cultured synovial cells, induced by several apoptogenic stimuli, are significantly suppressed by TGFβ1 treatment, which may be closely associated with the anti-apoptogenic function of TGFβ1.

MATERIALS AND METHODS

Synovial cell culture

Synovial cells were isolated from synovial tissues obtained from 18 patients with rheumatoid arthritis (RA) who met the American College of Rheumatology criteria for RA at the time of orthopaedic surgery, as we previously described. In some experiments, synovial cells isolated from patients with osteoarthritis were also used in this study. The adherent synovial cells used in this study at third to fifth passages were less than 1% reactive with monoclonal antibodies, including CD3, CD68, CD20, and von Willebrand factor, which are defined as fibroblast-like synovial cells.

Induction of synovial cell apoptosis by several apoptogenic stimuli

Synovial cells were cultured with or without recombinant human TGFβ1 (5 ng/ml; R&D Systems Inc, Minneapolis, MN) for 48 hours in RPMI 1640 containing 2% bovine serum albumin. After incubation, apoptosis sensitivity in untreated or TGFβ1 treated synovial cells was examined by further incubation with anti-Fas IgM (1 μg/ml; for 12 hours; MBL, Nagoya, Japan), Z-Leu-Leu-Leu-aldehyde (LLL-CHO, 10 μM for 24 hours; Peptide Institute, Osaka, Japan), etoposide (50 μM for 24 hours; TopoGen, Inc, Columbus, Ohio), or C2-ceramide (50 μM for 24 hours; Sigma). Apoptosis of synovial cells was quantified by the presence of hypodiploid DNA+ cells, the presence of terminal deoxy (d)-UTP nick end labelling+ cells (TUNEL+ cells), activation of caspases, and disruption of mitochondrial transmembrane potential (ΔΨm) as previously described.

DNA fragmentation was estimated by the presence of hypodiploid DNA+ cells and TUNEL+ cells, determined by flow cytometry (Epics XL, Beckman Coulter, Hialeah, FL). Detection of hypodiploid DNA+ cells was done by propidium iodide staining (100 μg/ml; Sigma Chemical Co, St Louis, MO), and TUNEL was examined by Methyl DNA Fragmentation Kit (MBL, Nagoya, Japan).

Activation of caspases in synovial cells was studied by western blot analysis, colorometric protease assay and flow cytometry. Western blot analysis was done by

Abbreviations: DEVDase, Asp-Glu-Val-Asp ase; DiOC6, 3, 3′-dihexyloxocarboxyocamine iodide; ΔΨm, disruption of mitochondrial transmembrane potential; IETDase, Ile-Glu-Thr-Asp ase; LEHDase, Leu-Glu-His-Asp ase; LLL-CHO, Z-Leu-Leu-Leu-aldehyde; RA, rheumatoid arthritis; TGFβ1, transforming growth factor β1; TUNEL, terminal deoxy (d)-UTP nick end labelling.
enhanced chemiluminescence system (Amersham, Arlington Heights, IL, anti-caspase-3; Transduction Laboratories, Lexington, KY, anti-caspase-8; MBL, anti-caspase-9; MBL). Decrement of procaspase expression and/or the appearance of cleaved products indicate the activation of each caspase. In addition to western blotting, increment of an enzymatic activity of Asp-Glu-Val-Asp ase (DEVDase: caspase-3 like activity), Ile-Glu-Thr-Asp ase (IETDase: caspase-8 like activity), and Leu-Glu-His-Asp ase (LEHDase: caspase-9 like activity) was used for detection of activation in each caspase.

Enzymatic activity of DEVDase (intracellular DEVDase+) cells was detected by flow cytometry (Epics XL) by the use of DEVD substrate (Oncotrinimum, Inc, College Park, MD) as previously described. Enzymatic activity of both IETDase and LEHDase was examined by colorimetric protease assay kit (MBL), and the activity of IETDase and LEHDase was evaluated by a spectrophotometer at an optical density of 405 nm (Multiskan JX, LABSYSTEMS, Tokyo, Japan), according to the manufacturer's protocol.

Expression of Bcl-2 (anti-Bcl-2; Dako Japan, Kyoto, Japan), Bcl-xL (anti-Bcl-xL; Trevigen, Gaithersburg, CA), and Bax (anti-Bax; Santa Cruz Biotechnology, Santa Cruz, CA) in synovial cells was studied by western blotting, and a relative expression ratio of Bcl-2 to Bax and of Bcl-xL to Bax was calculated by the software NIH Image (1.61) as follows: density of Bcl-2 or Bcl-xL/density of Bax/β-actin. β-Actin (anti-β-actin; Sigma) was used as an internal control protein in western blotting.

Mitochondrial perturbation in synovial cells was examined by AΨm. The cells were treated with saturating amount of Dio56 (3,3'-dihexyloxacarbocyanine iodide, Fluorescent technology, Grothenhofstr, Austria) at 37°C for 15 minutes, washed, and analysed by flow cytometry. In some experiments, synovial cells were cultured in the presence of Z-Val-Ala-Asp-CH₂DCB (caspase inhibitor, 200 μM; Phoenix Pharmaceuticals, Inc, Mountain View, CA), and apoptosis of these cells was also examined.

Statistical analysis
Data were expressed as mean (SD). Differences between groups were tested for statistical significance using the Student's t-test. A p value <0.05 was considered significant.

RESULTS
Inhibition of Fas mediated mitochondrial perturbation in cultured synovial cells by TGFβ1
Although we did not find the cleaved products of each caspase, activation of caspase-3/-8/-9 in synovial cells by anti-Fas IgM was strongly suggested by western blotting (fig 1), which was confirmed by an enzymatic activity assay for DEVDase, IETDase, and LEHDase (table 1). Mitochondrial perturbation with DNA fragmentation in synovial cells was also clearly induced by anti-Fas IgM (table 1). Expression of procaspase-3/-8/-9 in synovial cells was not changed by TGFβ1 (fig 1), but TGFβ1 treatment significantly suppressed AΨm, activation of caspase-3/-8/-9, and DNA fragmentation of synovial cells induced by anti-Fas IgM (fig 1, table 1).

Effect of TGFβ1 for synovial cell apoptosis induced by other apoptogenic stimuli
We next examined whether TGFβ1 treatment protects mitochondrial perturbation induced by other apoptogenic stimuli. LLL-CHO, etoposide, and C2-ceramide, the chemicals triggering apoptosis in a mitochondria dependent fashion, induced AΨm with the presence of DNA fragmentation toward synovial cells (table 2). Z-Val-Ala-Asp-CH₂DCB did not inhibit AΨm of synovial cells in the process (data not shown), which supported the importance of the mitochondrial pathway in synovial cell death induced by LLL-CHO, etoposide, and C2-ceramide. Activation of both LEHDase and DEVDase was also clearly found in synovial cells treated with the chemicals, and TGFβ1 treatment significantly suppressed the above hallmarks for apoptosis (table 2). As we previously described, the relative expression ratio of Bcl-2 or Bcl-xL to Bax in synovial cells was increased by TGFβ1 (untreated synovial cells: Bcl-2 to Bax 0.56 (0.07) and Bcl-xL to Bax 0.88 (0.06)* and Bcl-xL to Bax 0.88 (0.06); p<0.01 v untreated

Rheumatoid synovial cells were cultured with or without TGFβ1 for 48 hours, washed, and further incubated with anti-Fas IgM for 12 hours. After cultivation, the percentage of hypodiploid DNA+ cells, percentage of TUNEL+ cells, AΨm, DEVDase activity, IETDase activity, and LEHDase activity were examined as described in the text. Note that apoptotic cell death of synovial cells induced by anti-Fas IgM was significantly suppressed by TGFβ1. Results are mean (SD) from six individual experiments. Anti-Fas IgM [−]: addition of control mouse IgM. OD of IETDase and LEHDase was described as OD/μg protein. *p<0.01.
cells. Results are the mean (SD) of five individual experiments. We found no difference in TGFβ1 induced inhibition for synovial cell apoptosis induced by anti-Fas IgM, LLL-CHO, etoposide, and C2-ceramide for 24 hours. After cultivation, the percentage of hypodiploid DNA* cells, percentage of TUNEL+ cells, ΔΨm, DEVDase activity, and LEHDase activity were examined as described in the text. Note that apoptotic cell death of synovial cells induced by LLL-CHO, etoposide, and C2-ceramide was significantly suppressed by TGFβ1.

**DISCUSSION**

Our series of studies have indicated that the growth promoting activity of TGFβ1 for synovial cells can, in part, be mediated by inhibition of synovial cell apoptosis. As reported in other cell types, activation of caspase-3/-8/-9 as well as ΔΨm was found in anti-Fas monoclonal antibody-treated synovial cells, whereas these hallmarks for apoptosis were markedly suppressed in TGFβ1 treated synovial cells.

Mitochondrial dysfunction in synovial cells was also induced by LLL-CHO, etoposide, and C2-ceramide, leading to the activation of caspase-3/-9 and DNA fragmentation. TGFβ1 treatment significantly suppressed apoptotic activity of LLL-CHO, etoposide, and C2-ceramide. As we previously reported, relative expression of Bcl-2 and Bcl-xL was increased by TGFβ1, which may prevent the release of cytochrome c and apoptotic cell death of synovial cells induced by the above chemicals. TGFβ1 mediated protection for the mitochondria may also be effective in Fas induced apoptosis in synovial cells.

Impaired apoptosis of synovial cells in rheumatoid synovial tissues is supposed to have an important role in the progression of synovial cell hyperplasia of patients with RA, but recent investigations have suggested its characteristic progression of synovial cell hyperplasia of patients with RA, as well as ΔΨm was found in anti-Fas monoclonal antibody-treated synovial cells, including basic and growth factors other than TGFβ1. Rheumatoid synovial tissue contains a variety of cytokines reported in other cell types, activation of caspase-3/-8/-9, as well as ΔΨm was found in anti-Fas monoclonal antibody-treated synovial cells, whereas these hallmarks for apoptosis were markedly suppressed in TGFβ1 treated synovial cells.
