Capability for daily activities in old people with rheumatoid arthritis: a population based study

M Kauppi, S Hartikainen, H Kautiainen, K Laiho, R Sulkava

METHODS

This undertaking forms part of the Kuopio 75+ study described previously. It comprises a population based health survey focused on the clinical epidemiology of diseases, medicines used, and functional capacity in people aged 75 years or more. A random sample of 700 subjects was drawn from the total population born before 1 January 1923 and living in the city of Kuopio, eastern Finland, on 1 January 1998 (n = 4518). Kuopio has a population of 86 000 inhabitants, 5.3% of them falling in the age group studied.

A geriatrician and a trained nurse carried out a structured clinical examination and an interview to assess the physical and mental status of 601 subjects (86% of the random sample) in 1998. Ninety nine subjects could not be examined (79 refused to participate, five could not be contacted, and 15 had died before the examination). Medical records from the municipal health centre, home nursing, local hospitals, and Kuopio University Hospital were available. Detailed analyses of the series and the methods of the study have been described elsewhere.

Activities of daily living (ADL) were evaluated by the Barthel index (range 0, help needed in all activities, to 100, independent in all tested activities). There are 10 items in the Barthel index, among them eating, toileting, personal hygiene, dressing, walking, and climbing stairs. More complex activities (for example, cooking, cleaning, laundry, taking medicines correctly, shopping, and using public transportation) were described by a scale of instrumental activities of daily living (IADL) (range: 0 to 8 points, 8 meaning no help needed), as introduced by Lawton and Brody.

A history of cognitive decline was obtained by interviewing the subject and the relatives and by examining medical records. The mini-mental state examination (MMSE) was used to screen for cognitive capacity. The diagnosis of dementia as Alzheimer’s disease, vascular dementia, or dementia caused by other general medical conditions was made according to the DSM-IV criteria of the American Psychiatric Association, and dementia with Lewy bodies was also noted. All dementia diagnoses were subsequently evaluated by a neurogeriatrician (RS). The diagnostic procedure has been described elsewhere.

Subjects with a diagnosis of chronic rheumatoid arthritis (including one whose true diagnosis was later found to be juvenile rheumatoid arthritis (JRA)) were identified and described previously. Rheumatoid arthritis is not distinguished from osteoarthritis in the papers in question. Juvenile rheumatoid arthritis (JRA) was identified and described previously. It comprises a population based study focused on the clinical epidemiology of diseases, medicines used, and functional capacity in people aged 75 years or more. A random sample of 700 subjects was drawn from the total population born before 1 January 1923 and living in the city of Kuopio, eastern Finland, on 1 January 1998 (n = 4518). Kuopio has a population of 86 000 inhabitants, 5.3% of them falling in the age group studied.

characterised (Table 1). Data on their ability to carry out activities of daily living were collected and compared with the corresponding data on participants without rheumatoid arthritis.

RESULTS

There were 16 people (15 women and one man) with rheumatoid arthritis in the cohort according to the basic data; thus the prevalence of clinical rheumatoid arthritis in the population was 16/601 (2.7%; 95% confidence interval, 1.7% to 4.5%). Their mean (SD) age was 80.0 (3.5) years, and the mean (SD) age in the control population was 81.2 (4.6) years in the control population. The mean duration of rheumatoid arthritis was 24.4 years (range 2 to 69). The onset of the disease in one patient was in 1929, when she was only 13 years old. Her true diagnosis was thus JRA, but it was decided to include her in the series. A hip or knee arthroplasty had been done in nine of the 16 cases. Seven patients were on low dose systemic glucocorticoid treatment and five were on a disease modifying anti-rheumatic drug (DMARD).

Eight patients (50%) with clinical rheumatoid arthritis obtained the best possible results in the Barthel index, which did not differ significantly from the figure for the control population (276 persons, 40%). Two patients (12%) in the rheumatoid arthritis group were unable to move, three (19%) could not walk, and five (31%) were not able to climb stairs. Seven (44%) could not dress without help. The proportion of severely disabled persons (Barthel index ≤25) was 19% (three patients) among the rheumatoid cohort, as against only 4% (29 cases) in the non-rheumatoid group. When the results were adjusted (for sex and age), there was no statistical difference in figures for daily activities (either ADL or IADL) between the patients with rheumatoid arthritis and the other people in the cohort (Fig 1).

Three patients with clinical rheumatoid arthritis (19%) compared with 78 (13%) in the non-rheumatoid population were long term residents in nursing homes or local hospitals. About the same proportions of elderly subjects with and without clinical rheumatoid arthritis suffered from dementia—four people (25%) in the rheumatoid arthritis group and 133 (23%) in the non-rheumatoid group. Three of four elderly patients (75%) suffering from dementia and rheumatoid arthritis lived in institutional care, compared with less than half (n = 57, 42%) of the demented non-rheumatoid elderly population. The three patients with rheumatoid arthritis and dementia were among the four with the worst Barthel index values (5, 15, and 60 respectively), and the IADL could not be evaluated in two of them (one of the available values was poor (1), while the other was 3). The ages of the four persons with rheumatoid arthritis and dementia were 85, 81, 80, and 77 years. Two of these had Lewy body disease, one had secondary dementia, and only one had Alzheimer’s disease. The one with JRA was not demented.

We divided the clinical rheumatoid arthritis group into three subgroups according to the duration of the disease (0 to 9 years; 10 to 29 years; and more than 30 years); there were five, six, and five patients in these groups, respectively. Severe disability was strongly associated with the presence of dementia but not with the duration of rheumatoid arthritis. The patient with JRA was not disabled (Table 1).

DISCUSSION

The percentage of elderly people in the population of the Western countries has increased during past decades and this progress is expected to continue. The proportion of persons aged 75 years or more in this population in 1998 was 5.3% and it will probably be 7.1% by 2020 (official statistics of the city of Kuopio, Finland). Senior citizens often suffer from chronic conditions, especially of the locomotor system.10–16 Population based data on the functional capacity of old people is indispensable in planning the resources needed in society to take care of them in the future. The ability to lead an independent life improves with better access to good care, but decreases dramatically for those with age related disabling conditions.17 Despite progress in the active treatment of rheumatoid arthritis, the disease is and probably will remain a prominent cause of some degree of disability in the population.18–21

This study involved a cohort of 700 old people in a Finnish city with a homogeneous population. The results can be considered representative of the population, as the participation percentage (86%) in the cohort was high and the subjects (601 persons) were thoroughly interviewed and studied. This including evaluation of their medical records. Their functional abilities were evaluated by ADL (Barthel index) and IADL (Lawton and Brody) scales,13–14 which are commonly used in studies on elderly populations and also in clinical practice, although less widely in rheumatology.

The prevalence of rheumatoid arthritis in this study population was 2.5%, and that of JRA 0.16%, bringing the overall prevalence of chronic arthritis (clinical rheumatoid arthritis) up to 2.7%. These figures are acceptable when the chronic nature and the peak incidence of the disease and the

risk of premature death among affected individuals are taken into account. However, a slightly lower frequency (1.7%) has previously been reported in Finland. The prevalence of rheumatoid arthritis in Oslo is reported to be only 1.4% in the age group 70 to 79 years, but figures there were also low among younger people. The main finding here was that the mean capability for daily activities among patients with clinical rheumatoid arthritis did not differ significantly from that in the rest of the population. However, the proportion of severely disabled people (Barthel index ≤ 25 points) among patients with clinical rheumatoid arthritis was high (19%), and their distribution in Barthel index and IADL values was slightly bipartite. Severe disability seemed to be associated with the prevalence of dementia. Probably persons with rheumatic physical disabilities need institutional care at an earlier state of dementia than non-rheumatoid persons with dementia. The prevalence of dementia did not differ significantly between the population based cohorts in our study; in some other studies, however, Alzheimer’s disease has been found to be less common in persons with rheumatoid arthritis. This may also be the case in our sample, as a rather low proportion (25%) of the rheumatoid patients with dementia had Alzheimer’s disease. The causes of dementia in the whole series (137 patients) have been reported earlier (Alzheimer’s disease, 64 (47%); vascular dementia, 32 (23%); Lewy body disease, 11 (8%); and other, 10 (8%)). The mean Barthel index and IADL score values of the all dementia patients in the series were 58 and 4, respectively.

Fried and associates have reported that specific pairs of chronic diseases are synergistically associated with different types of disability, well beyond the multiplicative effect of the two diseases independently. They conclude that for disability prevention, individuals manifesting one high risk chronic disease should be carefully screened for prevention of other diseases which might interact to cause disability. This may also be the case with the combination of rheumatoid arthritis and dementia. Thus the indirect costs of dementia are probably especially high in patients with rheumatoid arthritis (and other physically disabling conditions) and vice versa, and this should be taken into account when the total costs of active treatment of rheumatoid arthritis and dementia are assessed. The long term cost-effectiveness of expensive biological anti-rheumatic treatments for old people should be evaluated in the future.

The lack of significant difference in mean functional capacity among rheumatoid patients and the general population was surprising, but probably reflects active and effective treatment of rheumatoid arthritis patients in developed countries (including DMARDS, glucocorticoids, rehabilitation, and arthroplasty). Patients with the most severe rheumatoid arthritis had probably died before they could have entered our cohort. In a 25 year prospective study of rheumatoid arthritis, Reilly and colleagues found that a better long term prognosis was associated with milder disease and better functional capacity. Improving treatment of rheumatoid arthritis will probably lengthen the life expectancy of affected patients, increasing their numbers in the future. Maintaining their mobility in later life is important, because mobility difficulties have been found to predict further disability, loss of independence, and even death.

Conclusions

It was encouraging to find that, in terms of activities of daily living, the functional capacity of old people with clinical rheumatoid arthritis did not differ significantly from that of the non-reumatoid population. Unfortunately rheumatoid arthritis may lead to severe and even total disability at an individual level, especially when associated with dementia, and will thus remain a great challenge to the health care and social systems.
