ABSTRACT

Objectives Patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) have increased risk of cardiovascular disease (CVD). We investigated whether single nucleotide polymorphisms (SNPs) at autoimmunity risk loci were associated with CVD in SLE and RA.

Methods Patients with SLE (n=1045) were genotyped using the 200K ImmunoChip SNP array (Illumina). The allele frequency was compared between patients with and without different manifestations of CVD. Results were replicated in a second SLE cohort (n=1043) and in an RA cohort (n=824). We analysed publicly available genetic data from general population, performed electrophoretic mobility shift assays and measured cytokine levels and occurrence of antiphospholipid antibodies (aPLs).

Results We identified two putative risk loci associated with increased risk for CVD in two SLE populations, which remained after adjustment for traditional CVD risk factors. An IL19 risk allele, rs17581834(T) was associated with stroke/myocardial infarction (MI) in SLE (OR 2.3 (1.5 to 3.4), P=8.5×10^{-5}) and RA (OR 2.8 (1.4 to 5.6), P=3.8×10^{-5}), meta-analysis (OR 2.5 (2.0 to 2.9), P=3.5×10^{-5}), but not in population controls. The IL19 risk allele affected protein binding, and SLE patients with the risk allele had increased levels of plasma-IL10 (P=0.004) and aPL (P=0.01). An SRP54-AS1 risk allele, rs799454(G) was associated with stroke/transient ischaemic attack in SLE (OR 1.7 (1.3 to 2.2), P=2.5×10^{-5}) but not in RA. The SRP54-AS1 risk allele is an expression quantitative trait locus for four genes.

Conclusions The IL19 risk allele was associated with stroke/MI in SLE and RA, but not in the general population, indicating that shared immune pathways may be involved in the CVD pathogenesis in inflammatory rheumatic diseases.

INTRODUCTION

Patients with systemic lupus erythematosus (SLE) have a 2–10 fold increased risk of cardiovascular disease (CVD) compared with the general population, with the highest relative risk in younger patients and highest absolute risk in older individuals.1–3 Women with SLE in the age of 35–45 years have a 50-fold increased risk of myocardial infarction (MI) compared with the general population.4 Death related to active disease and infections have decreased, but mortality related to CVD shows no such decline.5 Instead, a slight increase in standardised mortality ratio due to vascular diseases has been reported.6 Today SLE is acknowledged as a unique risk factor for CVD by the American Heart Association.

Traditional risk factors cannot fully explain the increased risk for CVD in SLE, and a number of SLE-related risk factors have been identified, such as antiphospholipid antibodies (aPL) and renal impairment.6–10 Genetic predisposition is an important risk factor for SLE, and different risk genes are also connected to CVD. We have previously shown that a variant of interferon regulatory factor 8 (IRF8)11 is associated with development of ischaemic heart disease in SLE and that a variant of signal transducer and activator of transcription 4 (STAT4) is associated with aPL and ischaemic stroke.12 Other risk genes shown to be associated with CVD in SLE include mannose-binding lectin, C reactive protein and HLA-DRB1*04/*13.13–15 Recently, a large international association study identified 24 new SLE risk loci using ImmunoChip genotype data.16–17 In the present study, we examined if single nucleotide polymorphisms (SNPs) analysed by the ImmunoChip were associated with CVD in two large SLE cohorts and investigated possible functional effects of associated gene variants. We also investigated if identified risk gene variants were associated with CVD in patients with rheumatoid arthritis (RA) and in the general population.

PATIENTS AND METHODS

Patients and controls

The discovery cohort included 1045 patients with SLE from rheumatology clinics in Sweden. All patients fulfilled ≥4 American College of Rheumatology (ACR) 1982 criteria for SLE.18 The replication cohort included 1043 patients with SLE from the University of California, San Francisco (UCSF) Lupus Genetics project.19 All patients completed an extensive questionnaire, and the SLE diagnosis was confirmed by medical record review according to...

Genotyping and quality control

Genotyping of the SLE discovery cohort, SLE replication cohort and the RA cohort was performed using the Illumina ImmuNochip (for quality control, see supplementary methods).16 17 24

Statistical analysis

A logistic regression model with sex and disease duration included as covariates was used to test association between SNPs and CVD in the SLE discovery cohort. For the American–European population sex, disease duration and the first principal component for population stratification were included as covariates. The identification of SNPs associated with CVD in SLE included three steps. First, the four CVD variables were tested for association with the ImmuNochip SNPs using data from the discovery cohort. Next, the top 100 associated SNPs per variable were tested for association with CVD in the SLE replication cohort, and SNPs not achieving nominal significance (P>0.05) were excluded. Finally, SNPs with meta-analysis P<0.001 were chosen as candidates for functional follow-up. The identified interleukin 19 (IL19) and signal recognition particle 54 – anti-sense 1 (SRP54-AS1) SNPs were analysed in the RA cohort, including sex and disease duration as covariates. Resulting significant variants were included in a cross-disease meta-analysis of SLE and RA. In this meta-analysis, P<1.0×10⁻⁶ adjusting for 48 000 independent SNPs on the ImmuNochip were considered significant. In other analyses, p values <0.05 were considered significant. For more information on statistical and bioinformatic analyses, see supplementary methods.

Functional analysis

Electrophoretic mobility shift assays (EMSA) were performed using nuclear extract from Jurkat, LCL, K562, HUVEC cell lines and peripheral blood mononuclear cells (PBMCs) from healthy individuals (supplementary methods). Expression quantitative trait loci (QTLs) were analysed using GTEx datasets,25 and IL19 (R&D Systems), IL10 (Mesoscale Discovery) and aPL levels were measured (supplementary methods).13 12

Carotid ultrasound

Ultrasound scans were performed as previously described.26

RESULTS

Identification of risk loci for CVD in SLE

The allele frequencies of 137 213 SNPs were compared between patients with SLE in the discovery cohort with and without CVD. Initially, we asked if there are general risk genes for CVD in SLE and consequently analysed ischaemic stroke and/or MI (stroke/MI) as one variable. Next, we looked for subtype-specific risk gene variants analysing MI and/or angina (MI/angina) and ischaemic stroke and/or TIA (stroke/TIA) separately. Finally, venous thrombosis defined as pulmonary embolism and/or deep vein thrombosis (PE/DVT) was analysed. We identified eight SNPs at three different loci demonstrating an association with CVD in both the discovery cohort and in the replication cohort, all reaching P<0.001 in the meta-analysis (tables 2 and 3). The IL19 risk alleles were associated with stroke/MI, the SRP54-AS1 risk alleles, and the IL7 receptor (IL7R) risk alleles were associated with stroke/TIA. Functional studies did not indicate the IL7R risk allele to be important for CVD development (see the ACR criteria.18 The SLE patients were all of European decent, and age at diagnosis was similar in both populations, but patients in the replication cohort were younger at follow-up and had less CVD events (table 1). In the discovery cohort, the average age at first stroke/transient ischaemic attack (TIA) was 52 years and at first stroke/MI was 54 years (online supplementary table S1). Information regarding stroke and TIA was available for 814 patients in the SLE discovery cohort and data regarding TIA, and angina was not available for the replication cohort. Patients with RA (n=824) all fulfilled the 1987 RA classification criteria19 (online supplementary method/table S2). Healthy blood donors (n=2711) were recruited as previously described.21 Publicly available data from the CARDioGRAMplusC4D Consortium22 and the International Stroke Genetics Consortium23 were used for analyses of CVD in the general population (online supplementary methods). All participants gave their informed consent.

The three SNPs showing an association with stroke and/or MI in both cohorts and in the meta-analysis.

Supplementary file). No SNPs were associated with MI/angina or PE/DVT (data not shown).

The IL19 locus

Three SNPs in the IL19 gene (rs74148801, rs17581834 and rs11115958) showed an association with stroke/MI in both SLE cohorts and in the meta-analysis (OR 2.3 (1.5 to 3.4), P=8.5×10⁻⁴; table 2). All three SNPs are located in intron 1 of the IL19 gene and are in high linkage disequilibrium (LD) with each other (1000 Genomes, r²=1) (figure 1A). The association between stroke/MI and the IL19 risk allele remained significant when adjusting for known cardiovascular risk factors in a multivariable regression analysis (OR 2.03 (1.07 to 3.84), P=3.09×10⁻²; online supplementary table S4). The IL19 risk allele was not associated with SLE per se (online supplementary table S5), the ACR criteria (online supplementary table S6) or the SLICC-DI (SDI) (OR 1.30 (0.94 to 1.79), P=0.12). There was no association between the IL19 risk allele and intima-media thickness (IMT) (0.059 vs 0.063 mm, P=0.92) or presence of carotid plaque (27% vs 21%, P=0.47) in a subgroup of patients with SLE (n=202) examined by carotid ultrasound.

To clarify the function of the IL19 risk allele, we initially performed EMSAs to investigate effects on transcription factor binding at the locus. Nuclear extract from Jurkat cells stimulated with PMA/ionomycin or PBMC stimulated with interferon-α (IFN-α) demonstrated binding of a protein to the reference allele (C) but not the risk/alternative allele (T) (figure 1B,C). Nuclear extract from unstimulated Jurkat cells or PBMCs showed protein binding to the IL19 risk allele (figure 1A). The association between stroke/MI and the IL19 risk allele was not associated with SLE (online supplementary table S5), the ACR criteria, levels of aPL, IMT or carotid plaque (data not shown, all P>0.05).

EMSA analysis using nuclear cell extract from Jurkat, LCL, K562 and PBMCs showed protein binding to the SRPS4-AS1 risk locus but no distinct allele specific difference (data not shown). According to chromatin immunoprecipitation with DNA sequencing (ChIP-Seq) data from the ENCODE project, measured in 394 SLE patients, but no significant difference between patients with and without the IL19 risk allele was observed (24% vs 19%, P=0.41). Plasma-IL10 was measured in 243 patients and patients with the IL19 risk allele more often had elevated IL10 compared with patients without the IL19 risk allele (50% vs 22%, P=0.0038). SLE patients with high IL10 more often had elevated levels of anticytadilolin (aCL) IgM antibodies compared with patients with low IL10 (31% vs 14%, P=0.01). Given these results, we measured the levels of aCL in 781 patients with SLE and observed an association between the IL19 risk allele and elevated levels of aCL IgG (P=0.002), aCL IgM (P=0.002), anti-β₂ glycoprotein-I (anti-β₂GPI) IgG (P=0.0004) and antiprothrombin (n=494) IgG (P=0.04) antibodies. Furthermore, the IL19 risk allele showed an association with positive lupus anticoagulant (LA; n=311) test (P=0.03).

Basic and translational research

Signal transducer and activator of transcription 1 (STAT1) binds to the SRP54-AS1 locus. As STAT1 is crucial for IFN-α signalling, we tested recombinant STAT1 in the EMSA and showed that STAT1 is one of the proteins binding at the SRP54-AS1 risk locus, with a lower affinity to the risk allele (figure 2B). According to GTEx data, the three SNPs at the SRP54-AS1 locus affect the expression of signal recognition particle 54 (S54), protein phosphatase 2 regulatory subunit B gamma (PPP2R3C), SRP54-antisense 1 (SRP54-AS1) and family with sequence similarity 177 member A1 (FAM177A1) in multiple tissues (online supplementary figure 1A–D). These genes are all located close to the SRP54-AS1 risk locus (figure 2A). In addition, the SNP rs712306, in high LD (r²=0.7), with the SRP54-AS1 risk allele showed differential expression of FAM177A1 in the artery wall (P=3.9×10⁻⁶) (GTEx, online supplementary figure 1C).²³

The IL-19 and the SRP54-AS1 loci in RA and in the general population

In order to investigate if the six identified CVD risk variants were confined to patients with SLE, or could constitute a risk factor for patients with other inflammatory rheumatic diseases, we compared the allele frequencies of the risk gene variants in RA patients with, and without, CVD (table 4). Results show that all 3 IL19 gene variants were associated with stroke/MI in SLE and that allele frequencies of the risk gene variants in patients with and without stroke/MI were similar in RA and SLE (table 4). In addition, the IL19 risk alleles showed association with stroke/TIA in RA (OR 2.8 (1.4 to 5.6), P=3.8×10⁻³). The SRP54-AS1 risk allele did not show an association with CVD in RA (data not shown). When including patients with SLE and RA in a meta-analysis, the association with stroke/MI

remained (OR 2.45 (1.96 to 2.94), P = 3.5 × 10^{−7}, after Bonferroni adjustment for 48,000 independent SNP\(^{16}\) on the ImmunoChip \(P_{\text{adj}} = 0.017\)). Publicly available data of individuals in the general population showed no association between the \(IL19\) and \(SRP54-AS1\) risk variants and ischaemic stroke or coronary artery disease (see supplementary results).

**DISCUSSION**

The objective of the present study was to investigate possible associations between genetic variation and CVD in SLE, and we identified two new risk loci, namely \(IL19\) and \(SRP54-AS1\). The \(IL19\) risk locus is located in an interleukin gene cluster coding for several cytokines, including \(IL19\) and \(IL10\). Several SNPs in this region have previously been associated with SLE\(^{27,28}\) and CVD in both the general population\(^{29,30}\) and in a small SLE study of 52 individuals.\(^{31}\) However, none of these earlier identified SNPs are in high LD with the SNPs at the \(IL19\) risk locus identified here, and none of the previously described SNPs were associated with CVD in our dataset. The observation that our identified risk gene variants were not associated with CVD in the general population suggests that there exist at least partly different underlying mechanisms behind CVD in SLE and the general population. The clinical picture for patients with and without the \(IL19\) risk allele did not differ regarding the ACR criteria\(^{18}\) or the SDI.\(^{24}\) Thus, the higher frequency of strokes and MIs in the group with the risk allele is not caused by a more severe SLE disease. Furthermore, when adjusting for known CVD risk factors, the \(IL19\) risk allele association remained. Thus, our results suggest that the \(IL19\) risk allele is an independent risk factor for stroke and MI in SLE patients with European decent. The observation that the \(IL19\) risk allele also was associated with stroke/MI in patients with RA, but not in the general population, furthermore suggest that the gene variants identified could be confined to patients with an inflammatory rheumatic disease, or at least SLE and RA. However, this assumption needs to be confirmed in studies with patients with other diagnoses.

The \(IL19\) risk locus is a putative binding site for several TFs and is located in a region of open chromatin with predicted enhancer function in LCLs and CD4 and CD8-positive T cells.\(^{32,33}\) In our EMSA analyses, we observed differential binding to the \(IL19\) risk allele of nuclear extract from PBMCs stimulated with IFN-α and

activated Jurkat cells. Because extract from unstimulated cells did not show differential binding to the site, cell activation or high levels of IFN-α as observed in SLE seems to be a requirement for the expression of the relevant protein. Publicly available data identified IKAROS family zinc finger 3 (IKZF3) as one possible TF with differential binding to the two alleles. IKZF3 is important for regulation of B cell differentiation, and recently a SNP in the promoter region of IKZF3 was shown to be associated with SLE. Interestingly, expression of IKZF3 is regulated by IRF8, a TF involved in IFN signalling and associated with CVD in SLE. In conclusion, our EMSA analyses suggest that the IL19 risk locus functions as a cell activation-dependent regulatory region and that the IL19 risk allele abrogates the binding of a TF induced by IFN-α or T cell activation.

To examine if the IL19 risk allele affects gene expression, we used data from the GTEx project but found no difference in RNA expression. Next, we went on to analyse protein expression of genes located in the same topologically associated domain and measured IL19 and IL10 levels in the patients with SLE. Similar to previously identified SNPs with long-range functional connections, we found that the intronic IL19 risk allele affects expression of the IL10 gene, located at a distance of 30 kb from the IL19 locus. As IL10 is known to stimulate B cells and antibody production, we measured levels of aPL and indeed found elevated levels of both aCL and aβ2-GPI as well as LA in patients with the IL19 risk allele. As presence of aPLs is a known risk factor for CVD, especially stroke, these results suggest that the IL19 risk locus exerts a regulatory effect on IL10 expression, enhancing production of prothrombotic aPL by B cells. However, both aPL and the IL19 risk allele remained significantly associated with stroke/MI in the multivariable regression analysis other mechanisms are also possible. Recently, it was reported that IL10 enhances IFN-α-mediated endothelial progenitor cell (EPC) dysfunction and that levels of IL10 correlated with EPC function in SLE but not in healthy controls. Thus, there are several mechanisms whereby IL10 could exert a negative effect on the circulatory system in SLE with implications for cardiovascular pathology.

The SRP54-AS1 locus was found to be associated with stroke/TIA in SLE. This locus was not associated with a more severe SLE disease, aPLs or subclinical atherosclerosis suggesting a novel mechanism of action. Published ChIP-Seq data indicate that the SRP54-AS1 locus is located in a region with enhancer/promoter function in CD4, CD8, CD19 and CD14 positive cells with several TFs potentially binding to the locus, including STAT1. In fact, we demonstrated that STAT1 displays a lower affinity to the alternative allele. This is interesting given the enhanced expression of STAT1 observed in PBMCs of patients with SLE and its role in intracellular signalling following binding of IFN-α to the type I IFN receptor. According to the GTEx database, FAM177A1, SRP54, PPP2R3C and SRP54-AS1 are differentially expressed in individuals with the SRP54-AS1 risk allele. Noteworthy, FAM177A1 is differentially expressed in the artery wall and has previously been associated with neurogenetic disorders. Because FAM177A1 has unknown functions, further studies are needed to determine possible mechanisms connecting FAM177A1 and stroke/TIA in SLE.

The strength of the present study is the large number of patients with SLE and RA investigated, the detailed information regarding CVD events available and that cytokine levels and aPLs were measured in a large number of patients. Furthermore, the Immunochip has approximately 48,000 independent SNPs when LD is considered, and a conservative p value threshold for significance of meta-analysis would be $1 \times 10^{-8}$. When including both the patients with SLE and RA in the meta-analysis, the statistical analysis reached this level of significance. Limitations include that the patients in the replication cohort were younger at follow-up resulting in fewer CVD events compared with the discovery cohort and that aPL and stroke data were missing for 20% of patients in the discovery cohort. In addition, we did not have data regarding lipid levels for the patients but identified risk genes have no reported function in lipid metabolism.

In summary, we have identified two potential risk genes of importance for development of CVD in SLE and for IL19 possibly also in RA. SLE patients with the IL19 risk allele, associated with stroke/MI, more often had high IL10 and elevated levels of aPL. The SRP54-AS1 risk allele, associated with stroke/TIA in SLE, was found to likely affect expression of a number of genes. Strikingly, both identified loci seem to affect gene regulation, rather than protein structure. We could also show that the IL19 gene variant is associated with stroke/MI in both SLE and RA but not in the general population, which suggests the existence of shared mechanisms in the development of CVD in patients with inflammatory rheumatic diseases and this assumption deserves further studies.

**Acknowledgements** We would like to thank the patients and healthy volunteers for participating, Lisbeth Feurer, Rezvan Kiani and Karolina Tandre for technical assistance and collecting blood samples. Genotyping of the discovery and RA cohort was performed by the SNPStats Technology Platform, Uppsala.

**Contributors** DL, LR, JKS and AA designed the study. JD, SE, M-LE and DL performed the experiments. KJ-U performed the carotid ultrasound examinations. DL, ES, CB, KET, MF, IG, CS, AAB, SR-D and LC and LR collected the data. AA, KET, LA and DL performed the statistical analysis. DL, AA, KET, JKS, LR, ES, JD, A-CS, LAC, SR-G and M-LE analysed the data. DL, JKS, JD and LR wrote the manuscript. All authors approved the final version of the manuscript.

**Funding** This project was funded by the Swedish Research Council for Medicine and Health (D0283001, A0258801, E0226301 and E0395401), Knut and Alice Wallenberg Foundation (2011.0073), AstraZeneca-Science for Life Laboratory Research Collaboratorgrant (DISSECT), Swedish Society of Medicine and Ingegerd Johansson donation, Swedish Rheumatism Foundation, King Gustaf V’s 80-year Foundation, Torsten Söderberg Foundation, Uppsala County Council and Uppsala University Hospital (ALF), Stockholm County Council (ALF), Uppsala University, Swedish Heart-Lung foundation, Selander Foundation, Agnes and Mat Rudberg Foundation, Gustaf Prim Foundation and COMBINE. Work related to the UCSF cohort was supported by NIH grants U1-TR-00004, P60-AR-053308 and R01-AR-48400.
