C-REACTIVE PROTEIN: NOT ONLY A MARKER, BUT ALSO A CAUSE OF INFLAMMATION THROUGH METABOLIC REPROGRAMMING OF HUMAN MACROPHAGES

Introduction C-reactive protein (CRP) is an acute-phase protein produced in high quantities by the liver in response to infection and during chronic inflammatory disorders such as rheumatoid arthritis (RA). As a consequence, CRP is in widespread clinical use as a general marker of inflammation. Although CRP is known to facilitate clearance of cell debris by phagocytic cells by binding to its ligand phosphocholine on dead cells, it is still unclear whether CRP displays additional immunological functions.

Objectives Here, we set out to investigate whether CRP, which is present in high concentrations in synovial fluid of active RA patients, also plays a role in the orchestration of inflammation in the inflamed joint.

Methods Human macrophages were differentiated from blood monocytes of healthy volunteers, or sorted from synovial fluid of RA patients. Cells were stimulated with complexed CRP (c-CRP) and/or ligands for Toll-like receptors (TLRs) and NOD-like receptors (NLRs), mimicking the stimuli in the inflamed joint. Responsible signalling pathways were identified using specific inhibitors and the Sea-urchin embryo extract (SEA) assay. Metabolic pathways were assessed by measuring glucose and lactate levels.

Results Strikingly, we here provide evidence that CRP is not only a marker, but also a cause of inflammation by strongly amplifying the production of RA-associated pro-inflammatory cytokines. We show that complex formation of CRP as a result of inactivation by the CRP receptor I and II (FcγRI and FcγRIIa) leads to enhanced gene translation of pro-inflammatory cytokines through metabolic reprogramming, particularly through amplified glycolysis and fatty acid synthesis.

Conclusions These data indicate that CRP is not only a marker, but also a cause of inflammation in RA patients by selectively promoting RA-associated pro-inflammatory cytokine production by human macrophages, thereby exacerbating pathology. From a therapeutic point of view, inhibition of c-CRP-induced immune activation, e.g. by targeting the identified molecular mechanisms, may be a valuable tool to suppress inflammation.

SCLEROSTIN AFFECTS RANKL-MEDIATED OSTEOCLAST DIFFERENTIATION

M Newling, L Sridharan, D Baeten, J Den Dunnen. Department of Clinical Immunology and Rheumatology, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

Introduction Sclerostin is a Wnt inhibitor and has anti-anabolic effects on bone formation by negatively regulating osteoblast differentiation. The lack of sclerostin in humans and mice leads to a higher bone mass and bone strength known as sclerosteosis. Therefore, inhibition of sclerostin is currently investigated as a treatment against osteoporosis. Surprisingly, the genetic deficiency or pharmacological inhibition of sclerostin causes a deterioration of disease severity in a TNFα-dependent arthritis mouse model (hTNFtg). hTNFtg mice lacking sclerostin displayed enhanced joint inflammation, cartilage loss and bone erosion associated with an elevated number of osteoclasts within the joint.

Objectives We want to investigate the impact of sclerostin on osteoclast differentiation and bone erosion in arthritis.

Methods Sclerostin knockout (sost−/−) mice were crossed with hTNFtg mice to obtain sost−/−hTNFtg synovial fibroblasts. Co-cultures of synovial fibroblasts and wildtype bone marrow macrophages were analysed by TRAP staining. RANKL expression was measured by ELISA and cytokine expression by array analysis and Western Blot. Moreover, the influence of sclerostin on osteoclastogenesis was additionally analysed in mono-cultures.

Results In our co-culture system of synovial fibroblasts and bone marrow derived macrophages, fibroblasts from sost−/− hTNFtg synovial fibroblasts. Notably, no increased expression of receptor activator of NF-κB ligand (RANKL) was detectable in sost−/−hTNFtg fibroblasts even after stimulation with inflammatory cytokines. Interestingly, basal secretion of IL-1α, which is known to stimulate osteoclastogenesis, was higher in sost−/−hTNFtg fibroblasts. Accordingly, sclerostin inhibited osteoclastogenesis when administered in the pre-differentiation phase, whereas no effect was observed in the differentiation phase, indicating an inhibitory effect of sclerostin on osteoclast precursors.

Conclusions Sclerostin deficiency in hTNFtg synovial fibroblasts promotes RANKL-mediated osteoclastogenesis, which is most likely dependent on IL-1α.
