Results: Up to 1 January 2018 1909 people took the quiz: 
- 89% (1699) of these were over 50 
- 95% (1814) were female. 
- 21% (443) of these lived in postcode areas of the pilot sites. 1359 people were sent a follow up survey one month after taking the online quiz, and 10% (142) completed it. 27% of these were individuals living in the postcode areas of the pilot sites. When surveyed, of the 142 respondents: 
- 50% (71) of respondents had broken a bone in the previous ten years, 
- 72% (104) thought they were at risk of osteoporosis after taking the test, 
- 24% (34) had either booked or attended an appointment with their GP to discuss their risk. Visibility of the awareness campaign at the point of care increased uptake of the quiz and subsequent survey.

OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH CIRRHOSIS. CAN FRAX BE USEFUL FOR SCREENING?

E. Casado1, M. Arévalo, J. Prolla2, A. Lira1, L. Del Rio1, O. Valero1, M. Larroza1, J. Sánchez-Delgado1, J. Gracelos1, J. Reichemund1, J. Crema1, E. Rodríguez-González1, M. Vázquez1, I. Taulé1, J. L. Casado2, M. Vázquez1.

Background: Osteoporotic fractures are a serious complication in patients with cirrhosis. In addition to the high morbidity and mortality of the patients who suffer them, fragility fractures represent a high cost for Healthcare systems.

However, there are very few studies that evaluate the prevalence of osteoporosis and fractures in patients with liver cirrhosis different than primary biliary cirrhosis (non-PBC cirrhosis). There are also no clinical guidelines with recommendations for osteoporosis screening in these patients.

Objectives: To assess the prevalence of osteoporosis and fragility fractures in patients with non-PBC cirrhosis in our environment, and the associated risk factors.

Methods: From November 2015 to September 2017, outpatients older than 40 years diagnosed with non-PBC cirrhosis (any Child stage) were randomly included.

Demographic, clinical and analytical data (calcium, phosphorus, 25-hydroxyvitamin D and PTH) were collected from all patients. A bone densitometry, GE, Lunar Prodigy (DXA) and vertebral fracture assessment (VFA) were also performed, for the diagnosis of osteoporosis (T-score ≤−2.5), and vertebral fracture. The 10 year absolute fracture risk was calculated using FRAX (https://www.sheffield.ac.uk/FRAX/tool.aspx?country=4).

A descriptive statistic of the main variables was carried out, with univariate and multivariate analysis to assess which predictive factors could be related to the presence of osteoporosis and/or fragility fractures.

Results: Ninety-two patients were included (71% male and 29% female). Age 63±11 years. The etiology of cirrhosis was: alcohol (52%), hepatitis C virus (27%) and alcohol +hepatitis C virus (9%). Stage: Child A (80.4%), B (17.4%) and C (2.2%). Mean 25-hydroxyvitamin D was 18.5±18.8 ng/ml and PTH 51.8±23.0 pg/ml.

16 patients (17%) had osteoporosis by DXA, 54 patients (59%) osteopenia and 22 (24%) had a normal bone mineral density (BMD). 8 patients (9%) had suffered some fragility fracture (vertebral fracture in 6 cases).

The 10 year absolute risk for major fracture (vertebra, humerus, femur or radius) by FRAX without BMD was 5.7±4.5; and with BMD 4.7±4.9.

Conclusions: The prevalence of osteoporosis and fractures in patients with non-PBC cirrhosis, even in mild stages, is higher than in the healthy population, being more frequent in women and older patients.

The FRAX tool can be useful in the diagnostic screening of these patients.

PAIN RELIEF MANAGEMENT OF ACUTE OSTEOSPEROTIC VERTEBRAL FRACTURE IN A REAL LIFE STUDY

F. Bertolino1, G. Gandolini2, A. Venturini3, C. Cisari4, R. Lovato5, M. Longhi5, S. Farina5, E. Bertoldo1, R. Nui6, on behalf of Servatius GISMO study group.

1 Internal Medicine, University of Verona, Verona; 2 rheumatology, IRCCS Don Gnocchi Mil; 3Rhebilitation Unit, University of Padua, Padua; 4Orthopedic Unit, University of PO; Novara; 5Internal Medicine, Villa Berica Hospital, Vicenza; 6Orthopedic Unit, Galeazzi Institute, Milan; 7Rhebilitation Unit, Crema Hospital, Crema; 8Rheumatology Unit, University of Verona, Verona; 9Internal Medicine, University of SIena, SIena

Background: Among all osteoporotic fractures the painful vertebral fractures (PVF) are the minority and their management is challenging for the clinician because the evidences about the best approach are conflicting and of low quality. Moreover there are no guidelines or consensus of experts. A real life picture of the management of the PVF is lacking in the literature.

Objectives: The primary end point of the study is to describe the pharmacological and or non-pharmacological management of PVF through the record of use of individual classes, associations and sequences of drugs or procedures. Secondary end point is the outcome of treatment in term of pain, disabilities and quality of life.

Methods: We present the item analysis results of a multicentric cross-sectional observational study. 400 interviews will be collected consecutively about pain, disability, pharmacological, spinal orthoses and orthopaedic surgery after the diagnosis of PVF in postmenopausal women treated by orthopaedics, endocrinologists, geriatricians, physiatrists, neurosurgeons and E.R. physicians.

Pain and disability were quantified by NRS scale and by QUALEFFO-41. Data collected from the first 100 patients have been analyzed.

Results: One hundred postmenopausal women aged 73.1±7.49 y.o. (age of menopause 48.6±3.9 years, L1-L4 T-score –2.75±0.20. Total hip T-score –2.35±0.98) with a new or first PFV were recorded. About 49% of them had a previous vertebral fracture and 22% a previous non-vertebral fragility fracture, 27% was not on osteoporosis treatment. The interviews were collected 135±114 days from diagnosis of PV, 174±141 days from onset of pain. 92.3%±12% of subjects were treated for pain relief for a mean time of 98±12 days. Only 1.6% of cohort fractures has been noted as well, probably due to predisposing factors related to HIV infection, apart from the traditional risk factors.

Methods: We performed a cross-sectional study with HIV infected patients followed up in the Infectious Diseases Department of our centre from 2014 to 2016. P1NP and b-CTX values were determined and lumbar and thoracic spine radio-graphs made to assess presence of VF (Gentan grading scale). Other clinical and demographic data were collected retrospectively. P1NP and b-CTX values in the presence (VF group) and absence of fractures (non-VF group) were compared. Mean values were also compared with the Camargo cohort, comprised of 1080 healthy postmenopausal Spanish women, used as reference. Statistical analysis were made with STATA. All patients signed and informed consent, previously approved by the Hospital’s Ethics Committee.

Results: A total of 144 patients were included, 38 were women with a mean age of 56.4 years old and 106 men with mean age of 56.5 years old. 45–86% of the patients had at least one VF. No statistically significant differences were found between P1NP mean levels in the F and the non F groups, with values of 45.30 ng/ml (±17.59 ng/ml) and 49.48 ng/ml (±52.92 ng/ml) respectively, (p=0.52). Mean levels of b-CTX were 0.38 ng/ml (±0.18 ng/ml) in the VF group and 0.43 ng/ml (±0.22 ng/ml) in the non-VF group, again without significant differences (p=0.35).

Mean general b-CTX values in our population were 0.41 ng/ml (±0.21); 0.46 ng/ml (±0.20) in women and 0.39 ng/ml (±0.20) in men. Higher levels were found in HIV infected women than in the Camargo cohort (0.38±0.19 ng/ml), with statistical significance (p=0.03). Mean general P1NP values were 48.34 ng/ml (±29.47) 58.63 ng/ml (±32.9) in women and 44.95 ng/ml (±27.56) in men, with no statistically significant differences found when HIV infected women were compared with those of the Camargo cohort, (47.7±19.9 ng/ml) (p=0.06), although a trend towards higher levels in HIV infected women was observed.

Conclusions: In the present study no correlation between P1NP and b-CTX levels in HIV infected patients and incidence of vertebral fracture was found. P1NP and b-CTX mean values in HIV infected women in our study are higher than those of healthy postmenopausal Spanish women, which means a higher bone turnover in this population. More studies are needed to clarify the extent and clinical impact of this finding.

BONE REMODELLING BIOMARKERS IN HIV INFECTED PATIENTS

F. López1, J. Loarce1, C. Sobrino1, J.L. Casado2, M. Vázquez1.

1Rheumatology Department, 2Infectious Diseases Department, Ramon y Cajal University Hospital, Madrid, Spain

Background: Bone metabolism is an equilibrium of resorption and growth, maintained by many regulating factors. Several molecules have been identified that estimate bone turnover, being P1NP and b-CTX the most commonly used. Many studies have shown a relationship between their levels and metabolic bone disease, and possibly with risk of fracture. Human Immunodeficiency Virus (HIV) infected patients have lower bone mineral density (BMD), as documented on many studies. An increased incidence of

Scientific Abstracts

underwent to percutaneous vertebroplasty while 84.6%±17.1% had spinal orthoses. Pharmacological treatment for pain was prescribed to 98.2%±7.1% of subjects: acetaminophen (42%), tapentadol (24%), opioids (24%), NSAID (8%) and codeine with acetaminophen (4%). In 95% of patients with spinal orthoses drugs for pain were assumed. In about 40% of cases NSAID was switched to acetaminophen, in 18% opioid and tapentadol switched to NSAID or acetaminophen. Only a few titration of opioids/tapentadol were reported. Not adequate pain relief (NRS scale 6.2±2.1; QUALEFFO-41 pain score 70.1±14.2) and impairment quality of life (mean total QUALEFFO-41 score 65.1±20.1) were reported.

Conclusions: With the limits of the study design and low number of cases, preliminary data seem to confirm an inadequate pain relief in PVF. The emerging critical issues across all categories of physicians are the lag of diagnosis, the inappropriate use of acetaminophen, the missing titration of opioids or tapentadol. A definition of optimal management of acute vertebral fracture is missing due to conflicting and scarce evidences in this field predisposing to chronic pain and disability.

AB0994 IMPACT ON THE ADHERENCE AND PERSISTENCE OF DENOSUMAB VS WEEKLY BISPHOSPHONATE IN HEALTH-RELATED QUALITY OF LIFE IN POSTMENOPAUSAL OSTEOPOROSIS

G. Cadinò1, R. Cinzia1, R. Maggio2, 1Rheumatology, ASL LE, Casarsano; 2Internal Medicine, ‘Vera Delli Ponti’ Hospital, Scornazza, Italy

Background: Long term adherence and persistence in patients undergoing treatment for postmenopausal osteoporosis remains poor despite the proven efficacy of the therapy.

Objectives: In this study, we evaluated whether greater adherence and persistence in treatment can lead to an improvement in the quality of life.

Methods: A cohort of 268 patients, all women, in postmenopausal osteoporosis divided into two groups was evaluated: “DEN Group” (DEN) in treatment with denosumab (n=131) and “BIS Group” (BIS) in treatment with bisphosphonates (n=137). Table 1 shows demographic and clinical data. Patients were followed for 3 years with baseline, 6 month, 18 month, and 36 month evaluation. The evaluation criteria were the persistence in therapy and the self-reported treatment compliance, as well as the quality of life assessed with the 41-item Quality of Life questionnaire for osteoporosis (QUALEFFO-41) performed at baseline, at 18 and at 36 months.

Results: Table 2 shows the percentage of patients who abandoned treatment at different times with a statistical significance towards both 18 and 36 months. In the BIS the main reason for abandonment were the adverse events (gastrointestinal, dental interventions, etc.), in the DEN the abandonment was due to drop-out. In BIS, the most frequent reason for non-compliance with therapy was oversight, and most patients who continued treatment always used the drugs regularly on a mean daily dose of 20 mg. Thirty-three (35.1%) patients received systemic glucocorticoids in the past. The main comorbidities were history of cancer (n=19) and chronic inflammatory diseases (n=21) including asthma (n=7), chronic obstructive pulmonary disease (n=7) and rheumatoid arthritis (n=7).

A secondary osteoporosis associated with the cascade was diagnosed in 54 patients (54.5%) with the following causes: glucocorticoid-induced osteoporosis (n=22, 23.7%), benign hemophathies (mastocytosis, MGUS) (n=7, 7.1%), use of aromatase inhibitors (n=3, 3.1%), anorexia nervosa (n=3, 3.1%), alcoholism (n=3, 3.1%), pregnancy and lactation-associated osteoporosis (n=2, 2.1%), primary hyperparathyroidism (n=2, 2.1%) and hypercorticism (n=1, 1.1%). In addition, 11 cases (11.3%) were reported following a vertebroplasty procedure. Primary either postmenopausal or idiopathic osteoporosis was diagnosed in 48 patients (51.6%). A total of 29 (29.6%) patients previously received an anti-osteoporotic treatment. In six patients (6.3%), VFC occurred early (in the year) following discontinuation of an anti-osteoporotic treatment: 5 after denosumab and one 12 months after an infusion of zoledronic acid.

Conclusions: In conclusion, the observation, although numerically limited, notes that the use of denosumab in patients with postmenopausal osteoporosis leads to a greater persistence in treatment and a statistically significant adherence to therapy, which allows obtaining the maximum therapeutic effect of the therapy, also determining in 36 months of treatment an improvement in the quality of life, which is not achieved in subjects treated with bisphosphonates.

AB0996 VERTEBRAL FRACATURES CASCADE: POTENTIAL ETIOLOGIES AND RISK FACTORS

H. Che1, V. Breuil2, B. Cortet3, J. Pacou3, L. Chaupis4, F. Debias5, R.M. Javier6, N. Mehsen Crete7, S. Loiseau Peres8, T. Thomas8, C. Roux9, K. Brot10, C.HU Lapeyronie, Montpellier; C.HU Nice, Nice; C.HU Lille, Lille; C.HU du Vire, Vire; C.HU Poitiers, Poitiers; C.HU Hautepiere, Strasbourg; C.HU Bordeaux, Bordeaux; C.HR Orleans, Orleans; C.HU Saint Etienne, Saint Etienne; C.HU Cochin, Paris, France

Background: Vertebral fracture (VF) is the most common osteoporotic fracture, and a strong risk factor of subsequent vertebral fracture. Prospective studies have shown that a recent VF increases an imminent risk of a subsequent one, and attention has been paid recently to a possible cascade phenomenon i.e. the occurrence of multiples VFs in less than one year.

Objectives: This cascade could have severe consequences, and we prompted a study to identify potential causes of osteoporosis and risk factors.

Methods: Vertebral fractures cascade (VFC) observations were collected retrospectively between January 1st and April 30th 2017. VFC was defined as the occurrence of at least 3 vertebral fractures within one year. Patients with other etiologies than osteoporosis (i.e. malignant or traumatic VFs) were excluded. The cause of osteoporosis associated with VFC was the one returned by the physician at the time of diagnosis.

Results: Ninety-five observations of VFC (80% of women, mean age of 71 years) were collected in 10 centres (9 tertiary centres and 1 outpatient centre). The median number of incident VFs over 1 year was 4.3-11 Forty-five patients (45.9%) had a previous major fracture before the VFC and 65 (70.7%) had densitometric osteoporosis (T-Score ≤-2.5 SD either at lumbar or femoral site). Eighteen (19%) patients currently received oral glucocorticoids treatment at the time of VFC, with a mean daily dose of 20 mg. Thirty-three (35.1%) patients received systemic glucocorticoids in the past. The main comorbidities were history of cancer (n=19) and chronic inflammatory diseases (n=21) including asthma (n=7), chronic obstructive pulmonary disease (n=7) and rheumatoid arthritis (n=7).

Conclusions: The results of this retrospective study show that almost half of VFC occurred in patients with secondary osteoporosis. While they suggest that a care-related approach, which allows to obtain the maximum therapeutic effect of the therapy, also determining in 36 months of treatment an improvement in the quality of life, which is not achieved in subjects treated with bisphosphonates.

AB0998 BONE MINERAL DENSITY AT DIFFERENT SITES AS A PREDICTOR OF RIB FRACTURES: A CASE-CONTROL STUDY

H.L. Wu, M. Bukhari. Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, UK

Background: Rib fractures commonly occur as a result of direct trauma, though pathological causes have also been identified. Literature on the specific risk factors of rib fractures is scarce. There was an American prospective cohort study
which highlighted the relationship between risk factors of osteoporosis and rib fractures in older men aged 65 or above. It was observed that the incidence of rib fractures was 5.1/1000 years. Only 3% of rib fractures occurred with absence of trauma. Bone mineral density (BMD) is an important measure for predicting various bone fractures. However, prediction of rib fractures using BMD measurement in different body sites is not reported.

Objectives: To determine if reduction in femoral neck and lumbar spine BMD are predictive of rib fractures.

Methods: Patients referred from primary care to a DXA scanner in the north west of England between January 2006 and December 2016 were used in this study. Patients with a history of rib fractures at first scan were matched with controls who did not have any indication for scanning. Cases and controls were matched for age and gender. Differences in BMD at L1-L4 spine and the femoral neck were analysed using two-sample t test. Logistic regression models were fitted to analysis the association between lumbar spine and femoral neck bone and rib fracture occurrence. The fit of each model was compared using receiver operating characteristic (ROC) curves.

Results: A total of 1554 patients were included in the study (777 cases of rib fractures and 777 controls). Mean age for both cases and controls were 62.5 years (SD 12.0). 605 patients (77.9%) were female in both the case cohort and the controls. The mean T score in the lumbar spine is 1.00 in cases versus 1.10 in controls (diff 0.100 95% CI 0.0448, 0.142 p<0.001). The mean T score in the femoral neck is 0.812 in cases versus 0.935 in controls (diff 0.123 95% CI 0.108, 0.137 p<0.001). The odds of lumbar spine BMD and femoral neck BMD were 0.111 (95% CI 0.0640, 0.194, p<0.001) and 0.02029 (95% CI 0.009033, 0.00485, p<0.001) respectively. The areas under ROC curve (AUC) for lumbar spine BMD and femoral neck BMD were 0.623 and 0.733.

Conclusions: This study demonstrated that reduction in BMD at the lumbar spine and femoral neck positively correlated to the risk of rib fractures. Reduction in femoral neck BMD is a stronger predictor of the two. Prediction of rib fractures could be affected by other factors influencing lumbar spine and femoral neck BMD. Further work in different demographic groups should be done for comparison and analysis.
