Tuberculous spondylodiscitis remains a major global public health problem in endemic countries that affects mostly young adults in their most productive years. Thoracolumbar junction seems to be the most common site of the spinal column involvement in spinal tuberculosis (85%) and cervical spine is concerned in only 5% of cases. The delayed diagnosis, between 3 and 20 months, explains the frequency of neurological deficits which are found in proportions of 20% to 40%. For the diagnosis of spinal tuberculosis, magnetic resonance imaging is more sensitive imaging technique than x-ray and more specific than computed tomography. Antituberculous treatment remains the cornerstone of treatment. Surgery may be required in selected cases. With early diagnosis and early treatment, prognosis is generally good.

Conclusions: Cervical Pott's disease is a rare localization. The diagnosis is easy in front of the cervical signs. The conservative management of cervical spine immobilisation and antitubercular chemotherapy remains a sufficient attitude to healing. Surgery is reserved in case of neurological aggravation or spinal instability.

AB1047 CERVICAL POTTS DISEASE: 5 CASE REPORTS AND REVIEW OF LITERATURE

Background: Spinal tuberculosis (Pott’s disease) is the most common as well as one of the most dangerous forms of skeletal tuberculosis and accounts for 50% of all cases of skeletal tuberculosis. Pott’s disease is still common in developing countries. Although the thoracolumbar junction seems to be the most common site of the spinal column involvement, cervical localization is sparse and accounts for 2% to 5% of spinal tuberculosis. Furthermore, the incidence of neurologic complications in spinal tuberculosis varies from 10% to 43%.

Objectives: The purpose of this study was to perform an updated review and present our experience with 5 cases of tuberculosis of cervical spine, including clinical characteristics, diagnostic modalities and management of spinal tuberculosis.

Methods: A review of 5 cases of cervical Pott’s disease collected at the Department of Neurosurgery of National Institute of Neurology of Tunis over a period of 2 years, between 2011 and 2012 and an updated literature review.

Results: The average age of our patients was 35 years old with extremes ranging from 16 to 63 years old. There is a slight male predominance. The diagnostic delay is on average 6 months. The clinical manifestations were dominated by cervical pain (4 cases) and progressive spinal cord compression syndrome (3 cases). The biological inflammatory syndrome is found in only one patient. The intra-dural reaction to tuberculosis is positive in 4 patients. X-ray of the cervical spine, CT scan and magnetic resonance imaging were performed in all patients. All patients underwent a surgical resection. The medical treatment was administered to all our patients. The evolution was favourable, clinically and biologically, under antitubercular treatment.

Conclusions: Infectious saccroilitis is a rather rare rheumatological emergency that has a misleading semiology because of the deep condition of the joint, the germ responsible plays an important role in this semiology and in its evolution

Methods: This is a retrospective study of 42 patients who have been hospitalised in the LA Rabta for Infectious Sacroilitis from 1999 to 2017. the epidemiological data (age/sex) were recorded as well as the clinical radiological and biological data (symptoms, inflammatory assessment, x-rays, CT scan and/or IRM, biopsy).

Results: Forty two patients were included in this study. The average age is 36.7 years old, sex distribution is 19 women 23 men. Banal sprouts are responsible in 48.15% of cases: Staphylococcus aureus 28.8% eschirichia coli 17.07% and 2.38% streptococcus, the progression was favourable in 87.4% of the cases under appropriate antibiotic therapy for the rest: 23.8% deaths, 2.38% state of septic shock, 7.84% of complication inherent to the treatments.tuberculosis is responsible for 37.2% of infectious saccroilitis with a favourable evolution in 77.6%, a complication related to treatment is noted in 17.64%, a subcutaneous abscess 2.34%, multifocal bone tuberculosis 2.38%brucellosis saccroilitis is diagnosed in 14.65% of cases, the evolution is favourable in 75.11%, in 4.76% a rapid progression towards ankylosis was noted despite appropriate antibiotic therapy, 2.38%a progression towards brucellosis chronic.

Conclusions: Common germs are most responsible during infectious saccroilitis and seem to have the best prognosis, tuberculosis is responsible for various complications and its treatment is at high risk of iatrogenic which limits the therapeutic choice of the clinician. Chronicity is the most feared development during Brucella saccroilitis as antibiotic therapy is no longer effective.

AB1049 RHEUMATOLOGICAL MANIFESTATIONS DURING CHRONIC HEPATITIS C
H. Kchiri1, D. Kaffel2, H. Dabebi1, D. ISSAOUI1, H. Sahli2, W. Hamdi2, M. Elleuch3, M.M. Kchiri2, R. Debeche4, N. Maamouni1.1Gastroenterology, La Rabta Hospital, Tunis; 2Rheumatology, Kassab, Manouba; 3Rheumatology, La Rabta Hospital; 4Gastroenterology, Charles Nicolle Hospital, Tunis, Tunisia

Background: Chronic hepatitis C (CHC) is assimilated to a systemic disease because of his multiple extrahepatic manifestations notably rheumatological.

Objectives: The aim of this study was to determine the prevalence and the characteristics of rheumatological manifestations (RM) associated with CHC.
