El Medany9, on behalf of PRINTO Egypt.1 Rheumatology and Rehabilitation, School of Medicine Assiut University, Assiut;2 Pediatrics, School of Medicine Cairo University;3 Rheumatology and Rehabilitation, School of Medicine Ain Shams University, Cairo;4 Rheumatology and Rehabilitation, School of Medicine Banha University, Banha;5 Rheumatology and Rehabilitation, School of Medicine Suez Canal University, Ismailia;6 Pediatrics, School of Medicine Alexandria University, Alexandria;7 Rheumatology and Rehabilitation, School of Medicine Cairo University;8 Rheumatology, Darent Valley Hospital, Dartford, UK

Objectives: To set recommendations for the management of children and adolescents living with JIA and assess whether there is a room for combined methotrexate and leflunomide therapy, adopting treat to target approach.

Methods: the treatment guidelines were developed based on systematic review, local studies, formal consensus and feedback. Initiation of methotrexate or leflunomide was recommended for polyarticular JIA children who, after 3 month of treatment, did not respond to methotrexate or leflunomide monotherapy, or those whose DMARD dose could not be optimised; a new management step was introduced where a combination of both medications was administered. This was a multicentre study including 76 JIA patients who had been treated with the combination of methotrexate plus leflunomide. All patients were classified according to the International League of Associations for Rheumatology (ILAR) criteria.

Results: Out of the 76 children there were, oligoarthritis (34%), polyarthritis (31%), systemic JIA with synovitis (>4 joints) (20%), and psoriatic arthritis (15%). Mean age at initiation of combined therapy 10.2±3.4 years, mean disease duration is 9.4±4.8 months. The combined therapy was superior to methotrexate alone and did not significantly increase the risk of adverse events. ACR-Ped 30 was achieved in 64% at 3 months, 75% at 6 months. This was superior to methotrexate alone (37.3% and 53.8%; p<0.01 at 3- and 6-months respectively). At 1 year, 81% reached Ped 30, 74.5% reached ACR-Ped 50, 64% achieved ACR-Ped 70 whereas 51% met ACR-Ped 90 criteria. There were no serious adverse events. One of the two DMARDs was stopped in 51% of the children; of them: 25% were due to adverse events, clinical remission in 25% whereas 21% were switched to anti-TNF therapy according to guidelines due to ineffectiveness or loss of efficacy. All patients who had had uveitis responded well and achieved clinical remission.

Conclusions: For the children with polyarticular JIA who did not respond to monotherapy with methotrexate, combination of methotrexate and leflunomide treatment appeared to be efficacious and maintain a durable response. The current recommendation would be to use combined methotrexate and leflunomide in children with polyarticular JIA who are either intolerant to higher methotrexate doses or who did not have a satisfactory response to methotrexate. The combination should be considered prior to the use of a biologic agent.

IMPACT OF METHOTREXATE ON GROWTH IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

A. Faza1, M. Selmani, K. Oueniche, S. Miladi, S. Kassab, S. Chekili, K. Ben Abdelghani, A. Laatar. Rheumatology, Mongi Slim Hospital – La Marsa, Tunis, Tunisia

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of chronic inflammatory disease which could be responsible for functional impairment and severe growth disturbance. Conventional disease-modifying antirheumatic drugs, such as methotrexate (MTX), may improve growth velocity especially by regulating systemic inflammation.

Objectives: The objective of this study was to evaluate the effect of MTX on growth parameters in pre-pubertal children with JIA and to determine the factors affecting the growth velocity.

Methods: We assessed height and changes in the height standard deviation score (SDS) at disease onset, at the onset of MTX and at the last follow-up visit in a cross-sectional study of JIA children. All patients were pre-pubertal when MTX began and were followed for at least 6 months afterward. We compared growth parameters (height, growth rate, weight and body mass index (BMI)) in responders and non-responders to MTX. The growth rate was defined as the number of millimetres of height acquired during 1 year. Associations between changes in the height SDS and discrete variables were evaluated using chi-square or Fisher’s exact tests. The significance level was set at 0.05.

Results: We enrolled 36 pre-pubertal children with JIA (24 boys and 12 girls) who had been treated with MTX orally. Median patient age was 6.2 years at the onset of MTX and 8.4 years at the latest follow-up. The median disease duration was 2.7 years [2.5–5.3]. Twenty-one patients (58.3%) had oligoarticular JIA, 2 patients (5.5%) had systemic JIA, 10 (27.7%) had polyarticular JIA and 3 (8.3%) had enthesitis-related arthritis. Nineteen children (52.7%) had received corticosteroids during an average period of 1.7 years [0.6–3] with a mean of 10 mg/day of prednisone or equivalent. The median duration of MTX at the latest follow-up was 3.1 years [0.6–5.5] with a mean MTX dose of 10 mg/m²/week.

Conclusions: In our study, the increase in growth parameters in pre-pubertal children with JIA was associated with a better control of the disease activity under MTX therapy.

THERAPEUTIC DRUG MONITORING OF BIOLOGICALS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA): AN OVERVIEW OF CURRENT PRACTICE IN ANTI-TNF THERAPY

A. Nassar-Sheikh Rashid1, D. Schonenberg-Meinema1, A. De Vries2, T. Rispens2, T.W. Kuipers3, G. Wob irrit4, J.M. van den Berg1.1 Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Diseases, Emma Children’s Hospital, Academic Medical Center;2 Department of Immunopathology, Sanguin Diagnostic Services Amsterdam, Sanguin, Amsterdam, Netherlands

Background: Juvenile idiopathic arthritis (JIA) is the most prevalent paediatric rheumatic disease. Long term complications include physical disability and a decreased quality of life. Since the introduction of anti-TNF drugs for JIA, its prognosis has improved significantly. Personalised medicine is the next step to improve treatment in JIA. Anti-TNF trough levels and demonstration of the presence of anti-drug antibodies (ADA) could help individualise treatment decisions in JIA patients, but evidence supporting this is missing.
