Background: Cardiovascular (CV) morbidity and mortality are significantly greater in Rheumatoid Arthritis (RA) patients than in the general population. Acetylsalicylic acid (ASA) is known to be associated with a significant decrease in the incidence of CV events in patients at high CV risk, as we have recently demonstrated in patients with Systemic Lupus Erythematosus, but its effectiveness as primary prophylaxis in RA patients has not yet been addressed.

Objectives: To investigate the role of ASA in reducing the incidence of CV events in an Italian multicentric RA cohort from the GIRRCS (Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale).

Methods: The clinical charts of RA patients consecutively admitted to 4 GIRRCS centres for their 1st visit from November 1st 2000 to December 31st 2015, who, at admission, satisfied 2010 ACR/EULAR criteria for RA and had not experienced any CV event, were analysed. The incidence of CV events during follow-up was recorded at December 2016. Kaplan Meier curve and log-rank test were used to investigate differences in event-free survival. Cox regression analysis served to identify factors associated with CV event occurrence.

Results: Seven hundred and forty-six consecutive RA patients were enrolled and followed up for a median of 5.6 years (range 2.9–8.9 years). The incidence rate (IR) of CV events was 7.8/1000 person-years (pys) in the overall cohort. Patients were subdivided into two groups, namely ASA- (242 patients) and non-ASA-treated (504 patients). The IR of CV events was significantly lower in the ASA-treated with respect to the non-ASA-treated group (IR 1.7 vs 11.5/1000 pys; p = 0.0002). Furthermore, the CV event-free rate was longer in ASA-treated than in non-ASA-treated patients (log-rank test 12.3; p = 0.0004), Figure 1.

Conclusions: The incidence rate of CV events in our Italian multicentric cohort was lower than that reported in other European and non-European cohorts. Low-dose ASA may have a role in the primary prophylaxis of CV events in RA patients.

time in the low DAS categories. This supports that remission should be the primary T2T goal in RA.

FR0016  NO RELATIONSHIPS BETWEEN ACPA AND PERIODONTITIS IN EARLY RHEUMATOID ARTHRITIS

F. Mechiti1, C. Zehraoui1, M. Meddad2, S. Sahali1, M. Benidir1, S. Merad1, N. Saadi1, O. Cheikin1, N. bidil, C. Dahou1, 1Rheumatology, Mohamed Dabeghine hospital, 2Periodontology, Mustapha Bacha Hospital, 3Immunology, 4Bacterology, Dély brahim, institut Pasteur, Algiers, Algeria

Background: Proteins citrullination contributes to generate anticitrullinated peptide antibodies (ACPA) in rheumatoid arthritis (RA). Porphyromonas gingivalis (Pg) is one of main germs incriminated in the development of periodontitis (PD), it has an enzyme called peptidyl arginine deiminase which is able to citrullinate the host proteins.

Objectives: The aim of this study was to seek for a possible association between ACPA and periodontitis

Methods: We conducted a case-control study of 69 patients with early rheumatoid arthritis (<2 years), naive of biotechnology and 138 age- and sex matched healthy controls. Smokers, diabetics, and subjects who received dental care and those who used antibiotics in the previous 6 months were not included. Demographic data and ACPA were determined. A periodontal examination was performed to all participants. Subgingival plaque samples were analysed to seek for Porphyromonas gingivalis(Pg) in both population in the case of periodontitis.

Results: The mean age of our patients was 40.7±12.04, the mean duration of the illness was 14.30±7.78 months (extremes: 1–24 months). ACPA was detected in 88% of patients and the mean titre was 255.57±450.78. PD frequency was higher in patient with PR compared with healthy controls (43% versus 29%) and a significant association was found between PR and PD (p<0.03). Patients with RA had 2.46 (CI 1.12 to 5.39) higher odds of having PD compared with healthy controls. In early RA, ACPA titre and rate was not associated with PD (p=0.06,p=0.44 respectively). Regarding the frequency of Porphyromonas gingivalis, there was no significant difference between the PR group and the control group (p=0.45). In addition, there was no significant difference between RA group and controls (p=0.68) concerning Porphyromonas gingivalis and ACPA

Conclusions: Periodontitis is a risk factor for the occurrence of rheumatoid arthritis. The ACPA does not seem to be related to periodontitis. In addition there was no association between ACPA and the presence of porphyromonas gingivalis.

FR0017  AN EXPLORATORY STUDY ON THE ROLE OF VITAMIN D SUPPLEMENTATION IN IMPROVING PAIN AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

G. Adams1, O. Viapiana1, L. Bogliolo2, F.P. Cantatore3, M. Varenna2, N. Malavolta2, A. Del Puente1, M. Muratore1, G. Orsolini1, D. Gatti1, M. Rossini1, on behalf of Study Group on Osteoporosis and Metabolic Skeletal Diseases of the Italian Society of Rheumatology (SIR). 1Rheumatology Unit, University of Verona, Verona; 2Rheumatology Unit, Policlínico San Matteo Foundation/University of Pavia, Pavia; 3Rheumatology Unit, University of Foggia, Foggia; 4Rheumatology Unit, Gaetano Pini Institute, Milan; 5Rheumatology Unit, University of Bologna Sant’Orsola-Malpighi Hospital, Bologna; 6Rheumatology Unit, University Federico II of Naples, Napoli; 7Rheumatology Unit, Galateo San Cesario Hospital, Lecce, Italy

Background: Lower serum vitamin D levels have been associated with various autoimmune diseases. Especially in patients affected by Rheumatoid Arthritis (RA), has been observed an inverse correlation between serum levels of 25-hydroxyvitamin D (25OHD), pain and disease activity, but the cause-effect relationship is not clear.

Objectives: The aim of this exploratory study is to investigate the effects of supplementation with cholecalciferol (vitD3) in improving pain and disease activity in RA patients with or without vitamin D deficiency (25OHD<20 ng/ml).

Methods: In this prospective open-label intervention study, patients fulfilling the EULAR/ACR 2010 criteria for diagnosis of RA, in non-remission (DAS28-CRP>2.6), on stable disease-modifying antirheumatic drugs, and whose treatment was not expected to be changed over a 3 month period following inclusion, were recruited. DAS28-CRP, VAS pain and serum levels of 25OHD, were evaluated at the baseline and after 3 months of supplementation with oral 100,000 IU/monthly of vitD3.

Results: A sample composed by 61 patients (47 females), with an average age (SD) of 58±12 years within 26–86 years range were included. At baseline the mean (SD) 25OHD levels were 2210 ng/mL. 57% of the patients were found to have vitamin D deficiency (<20 ng/mL). Mean serum 25OHD levels improved from 13±5 to 32±12 and from 29±7 to 41±10 ng/mL in patients with or without vitamin D deficiency, respectively. At baseline, mean VAS pain was significantly higher in patients with vitamin D deficiency. In the figure are shown DAS28-CRP and VAS pain at baseline and after 3 months of vitD3 supplementation both in patients with or without vitamin D deficiency. After large doses of VitD3, VAS pain significantly decreased in patients with vitamin D deficiency, while DAS28-CRP significantly improved only in patients without vitamin D deficiency at baseline.

Conclusions: VitD3 supplementation appears to be associated with significant and different effects on pain and disease activity in RA patients dependent on 25OHD serum levels. Vitamin D deficiency (<20 ng/mL) seems to be mainly correlated with higher pain, while higher levels of 25OHD might have immunomodulatory effects. A randomised, double-blind, low versus high vitD3 dose, placebo-controlled trial is recommended.

FR0018  THE ABILITY OF DISEASE ACTIVITY MEASURES TO PREDICT MAJOR THERAPEUTIC CHANGE IN US VETERANS WITH RHEUMATOID ARTHRITIS

G. Cannon1, C.-C. Teng1, N.A. Accort2, D.H. Collier3, T.-C. Lin4, B.C. Sauer5, 1Salt Lake City VA Medical Center and University of Utah, Salt Lake City, 2Amgen, Thousand Oaks, USA

Background: Current rheumatoid arthritis (RA) treatment guidelines recommend the use of disease activity measures (DAMs) to guide RA therapy. These guidelines recommend considering escalation of therapy in RA patients with high or moderate disease activity. Recent work by our group has demonstrated that many RA patients with high/moderate RA by Disease Activity Score with 28 joints (DAS28) did not have therapy escalated despite active disease (DAS28 >3.2).

Objectives: To determine if the rate of major therapeutic change (MTC) for RA patients with high/moderate disease activity based on DAS28 was similar when measured using two other common DAMs; 2) to compare the ability of different DAMs to predict MTC across the full spectrum of RA disease activity.

Methods: US Veterans enrolled in the VA Rheumatoid Arthritis (VARA) registry with 1) a complete set of DAMs (DAS28, Clinical Disease Activity Index [CDA], Routine Assessment of Patient Index Data 3 [RAPID3]) recorded (index date), 2) two other visits during the preceding 18 months separated by at least 60 days, and 3) clinical data available for 18 months prior to through 30 days following index date were eligible. Each patient was assessed for MTC within 1 week before and 30 days after index date. MTC was defined as any of the following: 1) initiation of new biologic or nonbiologic DMARD, 2) escalation of DMARD dose by ≥25%, 3) initiation of prednisone (as new agent or after 90 day gap during baseline), or 4) increase in monthly average prednisone dose by ≥25% and/or ≥5) injection of 2 or more joints with corticosteroids. MTC was analysed by DAM severity thresholds of 1) high, moderate, low, and remission, and 2) high, high/ moderated, and high/moderate/low levels. Analyses of the latter thresholds included sensitivity, specificity, predictive values, and accuracy estimations for MTC at each DAM level.

Results: Of 1776 eligible patients, 89% were male, mean age was 63.4 years, mean disease duration was 13.4 years, 79% tested positive for rheumatoid factor, 20% had no evidence of active disease (DAS28 ≤2.6), 66% had low DAS28, 15% high DAS28, and 15% moderate DAS28. The ability of each of the three DAMs to predict MTC was compared using receiver operator characteristic curves. The area under the curve for CDA was higher than for DAS28 (0.81 vs. 0.77) for predicting MTC. Of note, the area under the curve for RAPID3 was not significantly different from the other two measures. For high/moderate disease activity, the area under the curve for CDA was higher than for DAS28 (0.71 vs. 0.64), but both measures had low discriminatory power compared to the other two DAMs.

Conclusions: Rheumatologists should consider the use of non-DAS DAMs to assess disease activityputative MTC in US VA patients with high/moderate RA.
