RA and in biologic-treated patients than in controls (p<0.005). On brain MRI scans, there were significantly more vascular lesions both in the left and the right side in RA patients (55.1%–53.1%) than in controls (23.5%–20.1%) (p<0.05), the cerebral atrophy is much more common in RA (0.26 vs. 0.33;p<0.05).

Conclusions: These findings suggest that the presence of neuropsychiatric manifestations and cognitive impairment in RA patients is significant. Biologic-treated patients may represent a more severe RA subset thus having cognitive dysfunction more commonly. Brain atrophy, emollients and vascular lesions are more often in RA patients than controls.

ASSOCIATION OF BODY COMPOSITION WITH DISEASE ACTIVITY AND DISABILITY IN RHEUMATOID ARTHRITIS

K.M. Son1, S.Y. Lee2, S.H. Kang3, Y.I. Seo3, H.A. Kim3. 1Hallym University; 2Dongtan Sacred Heart Hospital; 3Hallym University Sacred Heart Hospital, Gyeonggi-Do, Korea, Republic Of

Background: Rheumatoid arthritis (RA) is a chronic form of inflammatory arthritis characterised by multiple joint involvement and significant disability. Previous studies showed that RA is associated with considerable changes in body composition, lipid profile, adipokines and insulin sensitivity

Objectives: To explore the association of body composition with pain, disease activity and disability in rheumatoid arthritis (RA)

Methods: Three hundred thirty five patients with RA visiting the Hallym University Sacred Hospital underwent body composition measurement with inbody analyzer and examined the disease activity score (DAS28). The association of body mass index (BMI), body fat mass and skeletal muscle mass with DAS28, DAS28-P (an index adjusted to measure the subjective component of DAS28), pain VAS and disability measured with the health assessment questionnaire (HAQ) was explored. Obesity was defined as BMI ≥25 kg/m². Pain VAS was dichotomized as ≤40 and>40. Low HAQ score was defined as ≤0.5. Logistic regression was divided in female versus male.

Results: Mean age of patients was 56±11.9 years and 84.8% were female. The median (IQR) disease durations was 6 (3.5–9) years and mean DAS28 score was 3.55±1.14. Mean BMI was 23.6±3.7 kg/m² and 109 patients (32.5%) were obese. Obese patients had higher CRP level (1.68 ml/dL vs 0 ml/dL, p=0.013), ESR level (25 mm/hr vs 18 mm/hr, p=0.032), pain VAS score (40 vs 35, p=0.045), and higher DAS28-ESR score (3.75±1.18 vs 3.46±1.11, p=0.031), than non obese patients. In multivariable regression analysis, DAS28 score in female was positively associated with current steroid dose, HAQ and body fat mass. In univariable logistic regression, higher pain VAS category in female was associated with older age, higher BMI and higher body fat mass. In multivariable logistic regression analysis, higher HAQ score in female was associated with older age, higher DAS28, higher body fat/skeletal muscle ration and lower skeletal muscle mass. In multivariable regression analysis, DAS28-P score in female was positively associated with higher body fat/skeletal muscle ratio and negatively associated with positivity of anti-CCP.

Conclusions: Body compositions such as body fat mass and skeletal muscle mass are significantly associated with pain and disability in RA patients

ASSOCIATION OF PSYCHOLOGICAL STRESS WITH SOMATOSENSORY DYSFUNCTION IN RHEUMATOID ARTHRITIS

L. Costa1, J. Vollert4, C. Maier4. 1São João Dongtan Sacred Heart Hospital; 2Pain Unit, Centro Hospitalar de Porto, Portugal; 3Division of Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands

Objectives: To explore the association of body composition with pain, disease activity and disability in rheumatoid arthritis (RA)

Methods: Two hundred sixty one patients with RA visiting the Hallym University Sacred Hospital underwent body composition measurement with inbody analyzer and examined the disease activity score (DAS28). The association of body mass index (BMI), body fat mass and skeletal muscle mass with DAS28, DAS28-P (an index adjusted to measure the subjective component of DAS28), pain VAS and disability measured with the health assessment questionnaire (HAQ) was explored. Obesity was defined as BMI ≥25 kg/m². Pain VAS was dichotomized as ≤40 and>40. Low HAQ score was defined as ≤0.5. Logistic regression was divided in female versus male.

Results: Mean age of patients was 56±11.9 years and 84.8% were female. The median (IQR) disease durations was 6 (3.5–9) years and mean DAS28 score was 3.55±1.14. Mean BMI was 23.6±3.7 kg/m² and 109 patients (32.5%) were obese. Obese patients had higher CRP level (1.68 ml/dL vs 0 ml/dL, p=0.013), ESR level (25 mm/hr vs 18 mm/hr, p=0.032), pain VAS score (40 vs 35, p=0.045), and higher DAS28-ESR score (3.75±1.18 vs 3.46±1.11, p=0.031), than non obese patients. In multivariable regression analysis, DAS28 score in female was positively associated with current steroid dose, HAQ and body fat mass. THE ASSOCIATION OF PSYCHOLOGICAL STRESS WITH INFLAMMATION IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA – A STUDY DURING RHEUMATOID ARTHRITIS DEVELOPMENT

A.C. Boer1, R.M. ten Brinck1, A.W.M. Evers2, A.H.M. van Der Helm – van Maas3,1. 1Rheumatology, Leiden University Medical Centre; 2Medical and Neuropsychology, Faculty of Social and Behavioural Science, Leiden University and Department of Psychiatry, Leiden University Medical Centre, Leiden; 3Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands

Background: Within established Rheumatoid Arthritis (RA), stress can have pro-inflammatory effects by activating the immune system via the hypothalamic-pituitary-adrenal axis and the autonomic nervous system. It is unknown if stress-levels promote also inflammation during RA-development.

Objectives: We studied whether the psychological stress response was increased in Clinically Suspect Arthritis (CSA) and if this associated with inflammation at presentation with arthralgia and with progression to clinical arthritis.

Methods: In 241 CSA-patients, psychological stress was measured by the Dutch version of the Perceived Stress Scale (PSS) at first presentation and during follow-up. Systemic inflammation was measured by C-reactive protein (CRP) and joint inflammation by 1.5T-MRI of wrist-, MCP- and MTP-joints.

Results: At baseline, 10% of CSA-patients had a high psychological stress response according to the MIH-5. This was not different for patients presenting with or without an elevated CRP, with or without subclinical MRI-detected inflammation and for patients who did or did not develop arthritis. Similar findings were obtained with the PSS-10. When developing clinical arthritis, the percentage of patients with ‘high psychological stress’ increased to 31% (p=0.025); during the first year of treatment this decreased to 8% (p=0.200). ‘High psychological stress’ in non-progressors remained infrequent over time (range 7%–13%). Stress was associated with fatigue (p=0.003) and wellbeing (p<0.001).
