Results: Increased frequencies of ILC2 and ILC3 were observed in patients compared to controls, while decreased frequency of ILC1 was found in patients compared to controls (p<0.008, p=0.004, and p=0.006, respectively). We also found the expression of T cell surface markers, CD4 or CD8, on ILCs and their subsets. The results showed that decreased frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs, CD4<sup>+</sup>CD8<sup>+</sup> ILC1, CD4<sup>+</sup>CD8<sup>+</sup> ILC2, and CD4<sup>+</sup>CD8<sup>+</sup>CD336<sup>+</sup> ILC1 were found in patients compared to healthy controls (p=0.001, p=0.017, p=0.001, p=0.004, and p=0.002, respectively). Furthermore, frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs and CD4<sup>+</sup>CD8<sup>+</sup> ILC2 were positively correlated with the SLEDAI-2000 score (r=−0.548, p=0.005 and r=−0.619, p=0.001, respectively). Frequencies of CD4<sup>+</sup>CD8<sup>+</sup> ILCs and CD4<sup>+</sup>CD8<sup>+</sup> ILC1 were positively related with serum C3 level (r=0.519, p=0.008 and r=0.528, p=0.007, respectively), and were positively related with serum C4 level (r=0.623, p<0.001 and r=0.643, p<0.001, respectively).

Conclusions: In the present study, we demonstrated that frequencies of circulating ILCs and its subsets were altered in SLE patients and some subpopulations were negatively correlated with SLE disease activity.

FR10299 MUCOSAL-ASSOCIATED IN Variant T Cell Deficiency in Systemic Lupus Erythematosus is Related to an Intrinsic Defect in the C42/Calcineurin/NfAT1 Signalling Pathway

Y.-W. Park1, Y.-N. Cho1, H.-M. Jin1, S.-J. Kee1. Rheumatology, 1Laboratory Medicine, Chonnam National University Hospital, Gwangju, Korea, Republic Of

Background: Mucosal-associated invariant T (MAIT) cells contribute to protection against certain microorganism infections and play an important role in mucosal immunity. However, the role of MAIT cells remains enigmatic in autoimmune diseases.

Objectives: Here, we examined the level and function of MAIT cells in patients with rheumatic diseases.

Methods: 12 patients with systemic lupus erythematosus (SLE) and 12 patients with rheumatoid arthritis (RA) were included in the study. The MAIT cells were assessed by flow cytometry.

Results: Circulating MAIT cell levels were significantly reduced in systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients. In particular, this MAIT cell deficiency was more prominent in CD8<sup>+</sup> and double-negative T cell subsets, and significantly correlated with disease activity, such as SLE disease activity index (SLEDAI) and 28-joint disease activity score (DAS28). Interestingly, MAIT cell frequency was significantly correlated with natural killer T (NKT) cell frequency in SLE patients. IFN-gamma in MAIT cells was impaired in SLE patients, which was due to an intrinsic defect in the Ca2+-calcineurin/NFAT1 signalling pathway. In SLE patients, MAIT cells were poorly activated by alpha-galactosylceramide-stimulated NKT cells, thereby showing the dysfunction between MAIT cells and NKT cells. Notably, an elevated expression of PD-1 in MAIT cells and NKT cells was associated with SLE. In RA patients, MAIT cell levels were significantly higher in synovial fluid than in peripheral blood.

Conclusions: Our study primarily demonstrates that MAIT cells are numerically and functionally deficient in SLE. In addition, we report a novel finding that this MAIT cell deficiency is associated with NKT cell deficiency and elevated PD-1 expression. These abnormalities possibly contribute to dysregulated mucosal immunity in SLE.

FR10300 POLYMORPHISM OF 5,10-METHYLENETETRAHYDROFOLATE REDUCTASE (C677T) IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME, ITS ASSOCIATION WITH CARDIOVASCULAR LESIONS

Y. Seheds, S. Shevchuk, I. Kuvikova, O. Galatina. Rheumatology, Institute of invalid rehabilitation, Vinnytsya, Ukraine

Background: Many studies have been conducted to determine the role of genetic polymorphism in the occurrence of cardiovascular diseases. The pathogenetic significance of MTHFR polymorphism is the subject of intensive research, especially its connexion with lesions of the cardiovascular system. The frequency of C677T polymorphism in the 5,10-MTHF gene is poorly known in patients with antiphospholipid syndrome (APS), and its relationship with vascular lesions has not been assessed yet.

Objectives: The present study aimed to analyse the C677T mutation of the MTHFR gene and its association with endothelial dysfunction and clinical manifestations of cardiovascular lesions in APS.

Methods: We studied 82 patients with APS, including 34 (41.6%) with primary antiphospholipid syndrome (PAPS) and 48 (58.4%) with secondary antiphospholipid syndrome (SAPS). The analysis of the MTHFR C677T mutation was performed by PCR followed by digestion according to Frosst et al. All patients were assessed for the endothelium-dependent vasodilatation of brachial artery (EDVD), the thickness of the intima-media of the common carotid artery (IMT), the presence of atherosclerotic plaque (AP) and clinical manifestations of cardiovascular lesions.

Results: There were 10.8% of homozygotes (677- TT), 37.8% of heterozygotes (677-CT) and 51.4% of homozygotes (677-CC) in the control group, and the frequency of T-alleles amounted to 29.7%. The incidence of T-alleles was higher among the patients with APS than in the control group and was 35.4%. The prevalence of of homozygotes (677- TT), heterozygotes (677-CT) and homozygotes (677-CC) was not significantly different between the PAPS and SAPS groups (44.1%, 38.2%, 17.7% and 45.8%, 39.6%, 14.8% respectively p<0.05). The frequency of T-alleles was higher in PAPS group than in SAPS group (36.8% against 34.4%, respectively p<0.05). The analysis of structural and functional vascular lesions in homozygotes (677-CC), heterozygotes (677-CT) and homozygotes (677- TT) did not reveal significant differences in both mean values and the proportion of individuals with IMT thickness (0.86±0.03 mm, 0.88±0.05 mm, 0.90±0.03 and 35.3%, 38.5%, 51.7% respectively p<0.05) with decrease of EDVD (7.09±0.49, 6.32±1.0, 6.92±0.58 and 47.0%, 53.8%, 48.3% respectively p<0.05) and the presence of AP (26.5%, 23.1%, 48.3% respectively p<0.05). Although there was a tendency of IMT thickness increase and EDVD decrease for T-carriers. The proportion of persons with IMT thickness (>0.90 mm) and the decrease of EDVD BA (<8.0%) among the homozygote 677-TT was 3%–6.5% higher than that of the 677-CC homozygote. The frequency of clinical manifestations of cardio-vascular lesions (myocardial infarction, stroke, TIA) was in 1.2–1.8 times more often among the homozygotes 677- TT than 677-CC homozygote.

Conclusions: The mutation of the C677T of the MTHFR gene is not a risk factor for the development of atherosclerotic vascular damage in patients with APS, due to the lack of associative interrelationships between the decrease of EDVD, increase of IMT, clinical manifestations on the one hand, and the MTHFR polymorphism on the other.

FR10301 SERUM EXOSOMES INVOLVED IN THE PROGRESSION OF LUPUS NEPHRITIS

Z. Zhang, W. Xue, J. Ji, T. Fu, J. Yang, Z. Gu. Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that systemically affects several important organs. Lupus nephritis (LN) is one of the most severe complications of SLE. Exosomes are important mediators of biological information and play a part in the occurrence and development of various diseases including LN.

Objectives: The aim of study was to find whether exosomes participate in the pathogenesis of lupus nephritis.
