THE PRESENCE OF ANTI-RITUXIMAB ANTIBODIES PREDICTS INFUSION-RELATED REACTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Wincup, M. Menon, E. Smith, E.C. Jury, D.A. Isenberg, C. Maurion behalf of ABIRISK Consortium. *Rheumatology, University College London, London, UK*

Background: Rituximab is a genetically engineered chimeric anti-CD20 monoclonal antibody commonly used in the treatment of a variety of autoimmune rheumatic conditions. Although generally well tolerated, serious infusion related reactions can occur and are difficult to predict. It has previously been suggested that patients with systemic lupus erythematosus (SLE) who are treated with Rituximab demonstrate a higher incidence of infusion reactions and a less predictable response to the therapy when compared with other diseases.

A major limitation of biologic therapies is the development of anti-drug antibodies (ADA). To date the presence of ADAs to Rituximab have not previously been explored in detail.

Objectives: To assess the prevalence of ADAs to Rituximab in patients receiving treatment for SLE and how the presence of these antibodies relates to:

1. the incidence of infusion-related reactions
2. the therapeutic efficacy of the drug

Methods: We assessed the presence of Rituximab ADAs using a Meso Scale Discovery platform in 58 SLE patients treated with Rituximab at University College London Hospital, UK. A subgroup of 42 patients were followed up longitudinally for up to 8 years after their first dose of Rituximab. Clinical parameters including BILAG, complement C3 levels, anti-double-stranded DNA (dsDNA) antibody titres, lymphocyte count and frequency of CD19⁺ B cells were recorded. A retrospective review of patient notes was undertaken to assess for a history of infusion related reactions. Mann-Whitney U test was used to compare variables between the ADA positive group and ADA negative group.

Results: A total of 58 patients were recruited of which 88% were female (51/58). Median age was 38.9 years old with a median disease duration of 84 months. ADAs to Rituximab were detected in 60% (35/58) of patients. In those with a positive ADA (n=35), 22 were later retreated with Rituximab. Infusion reactions were noted in 68% (15/22) of those undergoing retreatment in the context of a previously positive ADA. In the remaining patients who were retreated but in which no infusion reaction was seen (7/22), the average level of ADA was significantly lower than in those who did have a reaction (median in those who suffered a reaction=200 unit; median in those who were ADA positive but did not develop a reaction on retreatment=10 units; p=0.008). There were no reactions observed in patients that did not display ADAs who were subsequently retreated.

In the first six months post-Rituximab there was no statistically significant difference in BILAG, C3 levels, dsDNA titres, lymphocyte count or CD19 between the groups in which ADAs were present when compared with those in which ADAs were absent.

Conclusions: For the first time, ADAs to Rituximab have been described in a cohort of SLE patients who have undergone B-cell depletion therapy. High levels of circulating ADAs to Rituximab were found in patients who later developed infusion reactions on retreatment. However, there was no obvious difference in clinical outcomes between those who were ADA positive compared with those in which it was negative. Together, this suggests the presence of ADAs can predict future infusion reactions but do not adversely impact upon the efficacy of treatment.

In future, the routine screening of ADAs to Rituximab will help to reduce the risk of serious infusion reactions in patients being treated.

REASONS FOR HOSPITALISATION AND IMMUNOSUPPRESSANT USE IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ADMITTED TO A TERTIARY ACADEMIC MEDICAL CENTRE

C. Anastasiou¹, O. Dulai², A. Baskaran², J. Proudfoot², S. Verhaegen², K. Kalunian². ¹University of California San Diego and University of California San Francisco; ²University of California San Diego, San Diego, USA

Background: An estimated 22% to 28% of US SLE patients are hospitalised each year.¹ SLE and other connective tissue diseases have been ranked the sixth most likely conditions to result in 30 day readmission to the hospital.²

Objectives: To determine if the number of SLE patient hospital admissions, primary reasons for hospitalisation, and mortality have changed over time. We also sought to evaluate changes in immunosuppressant use in these patients.

Methods: A retrospective chart review was conducted on all adult patients with SLE admitted to the University of California San Diego Medical Centre in 2005 and 2013. Patients were identified by SLE billing code 710.0 of the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM).

Results: The number of yearly SLE patient hospitalizations decreased from 178 to 86 between the two times of observation. Infection was the most common reason for

hospitalisation accounting for 39.9% of hospitalizations in 2005 versus 31.4% of hospitalizations in 2013 (p=0.29). Lupus flare accounted for 9.6% of admissions in 2005 versus 8.1% of admissions in 2013 (p=0.722). SLE patient mean length of hospital stay decreased from 7.6 days to 6.4 days compared to all patient length of stay which decreased from 6 days to 5.75 days. Seven patients (3.9%) died during their hospitalisation in 2005 as opposed no inpatient deaths in 2013. Of the 261 admissions between 2010 and 2013, six admissions resulted in death (2.3%). Corticosteroid use decreased (79.8% to 61.6%, p=0.109), while hydroxychloroquine (27.0% to 59.3%, p<0.001), mycophenolate mofetil (5.6% to 13%, p=0.060), and leflunomide (0.6% to 9.3%, p=0.008) use increased over time.

Conclusions: Hydroxychloroquine and leflunomide use in hospitalised patients more than doubled from 2005 to 2013 with statistical significance. Rise in mycophenolate mofetil use and drop in corticosteroid use trended toward statistical significance. Number of hospitalizations, length of stay, and mortality decreased. Infection was the primary reason for inpatient hospitalisation and there was a decrease in admission for both infections and SLE flares between the time points although this did not reach statistical significance. We hypothesise that changing medication prescribing patterns may have altered the rate of damage accrual and mortality in SLE patients, and plan to perform a national study to further evaluate SLE hospitalisation data on a larger scale.

HEALTH CARE RESOURCE UTILISATION (HCRU) AND COST ANALYSES OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AS A FUNCTION OF DISEASE SEVERITY: ANALYSIS OF REAL-WORLD CLAIMS DATA FROM A GERMAN SICKNESS FUND

E.R. Hammond¹, H. Friedel², E. Garal-Pantaler², M. Pignot³, E. Velthuis⁴, X. Wang¹, H. Nab⁵, B. Desta¹, A. Schwarting⁶. ¹AstraZeneca, Gaithersburg, MD, USA; ²Team Gesundheit GmbH, Essen, Germany; ³Kantar Health GmbH, Munich, Germany; ⁴Evidera PPD, Utrecht Area, Netherlands; ⁵AstraZeneca, Cambridge, UK; ⁶Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany

Background: SLE is a severe, chronic autoimmune disease of the connective tissue involving multiple organ systems. Understanding the economic burden of SLE in the context of disease severity is important when considering new therapeutic options.

Objectives: HCRU and costs associated with SLE were examined retrospectively using anonymized data from a German Sickness Fund database.

Methods: Real-world claims for adult (≥18 years old) patients (pts) with SLE from a German Sickness Fund database of company health insurance schemes were analysed. HCRU and costs were assessed annually for 2009–2014 for pts diagnosed with SLE in 2009 and validated using repeated SLE-related claims, co-diagnosis codes, laboratory tests, prescription treatment, and the diagnosing physician's specialty. Pts had to have data available for 2009 and ≥3 years before the index quarter in 2009. HCRU and costs for SLE cases were compared with those of controls matched (4:1) by age, sex, and baseline Charlson Comorbidity Index (CCI). Continuous outcomes were compared with a nonparametric test (e.g., Wilcoxon-Mann-Whitney) because most outcome distributions were positively skewed.

Results: Of the 3,290,701 persons with data available for 2009 and ≥3 years prior, 1228 had an SLE diagnosis in 2009. SLE prevalence steadily increased from 37.32/100,000 (incidence: 5.96/100,000 per year) in 2009 to 47.36/100,000 in 2014. The final sample comprised 1,160 SLE-confirmed pts (mean age: 52 years; females: 84%; baseline CCI range: 1–13). Most (85%) pts were diagnosed with SLE before 2009 SLE disease severity at baseline was classified as mild for 148, moderate for 484, and severe for 528 pts using a combination of International Classification of Diseases-10 GM and medication/procedures codes. Compared with matched controls, SLE pts, overall and those with moderate and severe disease, had significantly greater mean annual medical costs in 2009 (all SLE: € 6895 vs. € 3,692; moderate SLE: € 4867 vs. € 3,380; severe SLE: € 10,001 vs. € 4,239; p<0.0001 for each comparison) and each year thereafter. Mean costs, total number of hospital days, numbers of outpatient visits, hospital stays, and outpatient prescriptions, and other benefits were significantly greater for all
