Background: Lumbar multifidus is a muscle which is responsible for lumbopelvic stability primarily. Foot-ankle posture and function disorders affecting the lumbopelvic region muscles and biomechanics, cause increased stress in the lumbopelvic region and may cause low back pain in many studies (1,2,3). However, it is not known whether the lumbar multifidus muscle is affected by this condition (4,5).

Objectives: Plantar pressure distribution can change due to foot-ankle postural disorders. Our aim is to examine whether the plantar pressure distribution affects the lumbar multifidus muscle thickness.

Methods: 40 healthy young adults aged 18 to 25 years were included in the study. Static and dynamic pedobarographic assessments were performed to determine the plantar pressure distribution, on a 3x1 meter sensored walking platform with the DIASU Digital Analysis System®. Peak pressures (N/cm²) of 9 zones of the foot (medial of heel, lateral of foot, 5 metatarsal, thumb and 2.3.4 and 5. digits) were recorded. Ultrasonographic imaging was used to assess lumbar multifidus muscle thickness.

Results: There was statistically significant correlation between lumbar multifidus muscle thickness and peak pressure medial of heel and 1. metatarsal bone in static pedobarographic analysis (p<0.05). As the peak pressure on the medial part of foot increased, m. lumbar multifidus muscle thickness was reduced. There was statistically significant correlation between lumbar multifidus muscle thickness and pressure medial of heel and 2.3.4. and 5. digits in dynamic pedobarographic analysis (p<0.05). As the peak pressure on the medial part of foot increased, m. lumbar multifidus muscle thickness was reduced.

Conclusions: This study showed that plantar pressure distribution affected lumbar multifidus muscle thickness. Based on these results, the lumbopelvic region and foot posture should be considered in therapeutic interventions.

EFFICIENCY OF COMPLEX REHABILITATION PROGRAM IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ABATACET

FR10684

E. Orlova1, D. Karateev2, A. Kochev1. 1Department of Rehabilitation Medicine, Federal Medical Biological Agency, 21st Department of Internal medicine, Moscow Federal Medical Biological Agency, 21st Department of internal medicine, Moscow Regional Research and Clinical Institute (“MONIKI”), Moscow, Russian Federation

Background: Rehabilitation techniques (physical exercises, physiotherapy, occupational therapy, patient education) help to manage rheumatoid arthritis (RA) in addition to drug treatment [1–4].

Objectives: To evaluate the efficiency of 12-month complex rehabilitation program in patients with RA receiving abatacept.

Methods: 50 patients with RA (94% females, 72% with moderate disease activity by DAS28, age of 18 to 57 years, disease duration of 10 months to 12 years) were included and randomized into 2 groups. All patients received abatacept (intravenously 10 mg/kg (mean 750 mg) every 4 weeks or subcutaneously 125 mg once a week) with methotrexate 20–25 mg per week. 28 study group patients underwent 12-months complex rehabilitation program: laser therapy of 12 to 16 min (infrared low intensity laser radiation, wavelength of 0.89 micrometers, pulse frequency of 1000 to 1500 Hz) for hand, knee, ankle, shoulder and elbow joints, 3 courses for 14 sessions with a mean interval of 3.2 months; 45-min dynamic exercises using gym apparatus Enraf-Nonius under the supervision of a trainer 3 times a week; 45-min exercises for hands 3 times a week; 45-min occupational therapy (joint protection strategies, use of assistive devices and adaptive equipment), 10 sessions; wrist, ankle and knee orthoses, orthopedic insoles; education program (4 daily 90-min studies). 22 patients received only drug treatment (control). Tender and swollen joint count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), joint pain on 100-mm VAS, DAS28, HAQ, RAPID3, hand grip strength, the average powers of knee extension and ankle flexion by EN-TreeM movement analysis were evaluated at baseline and at 12 months.

Results: After 12 month in the study group tender joint count decreased by 69.9% (p<0.01), swollen joint count – by 66.2% (p<0.01), ESR – by 63.7% (p<0.01), CRP – by 56.5% (p<0.01), pain on VAS – by 82.3% (p<0.01), DAS28 – by 39.6% (ΔDAS28=2.89±0.99, p<0.05), HAQ – by 72.2% (ΔHAQ=1.73±0.44, p<0.01), RAPID3 – by 78.3% (ΔRAPID3=8.45±0.85, p<0.01). The grip strength of a more affected hand enhanced by 57.1% (p<0.01), of a less affected – by 46.2% (p<0.05). The average extension power of a weaker knee increased by 72.1% (p<0.01), of a stronger – by 65.8% (p<0.01). The average flexion power of a more affected ankle joint elevated by 48.9% (p<0.05), of a less affected – by 69.4% (p<0.01). In the study group there were statistically significant differences from the control group in the most parameters (p<0.05), excluding CRP, ESR, DAS28 and the average flexion power of a more affected ankle joint (p<0.05).

Conclusions: 12-month complex rehabilitation program relieves pain, improves quality of life, functional status, motion activity and helps to control disease activity in patients with RA receiving abatacept.

HAND FUNCTIONS ARE AFFECTED DEPENDING ON THE CURVE PATTERN IN IDIOPATHIC SCOLIOSIS

FR10685

G. Yagci1, D. A. Ozcan2, C. Ayhan1, Y. Yaksu2. 1Physiotherapy and Rehabilitation, Hacettepe University, Ankara, 2Physiotherapy and Rehabilitation, Hasankoyunlu University, Gaziantep, Turkey

Background: Idiopathic scoliosis (IS) is a three-dimensional deformity and causes postural distortions in head, trunk, scapular region and upper extremities. Hand functions have not been evaluated in relation to lateral curvature of the spine in IS previously. There is a need to evaluate possible changes in hand functions with scoliotic curve in idiopathic scoliosis.

The Effect of Foot Orthoses on Balance in Individuals with Idiopathic Scoliosis

**Objectives:** The aim of this study was to investigate hand functions in individuals with idiopathic scoliosis.

**Methods:** Ninety-four individuals with mild or moderate idiopathic scoliosis ( Cobb angle range: 10°–45°) were included. Curves were classified as single thoracic (n=18), single thoracolumbar (n=33), single lumbar (n=22) and double curves (n=21). Assessments included hand dexterity with Minnesota test, hand reaction time with Nelson test, hand-eye coordination with finger-to-nose test, throwing accuracy with Functional Throwing Performance Test, and upper extremity stability with the Closed Kinetic Chain Upper Extremity Stability Test. One-way ANOVA was used to compare continuous variables between different curve pattern groups and a Tukey’s hsd means comparison was used to examine the nature of the significant difference found by ANOVA. In addition, Student’s t test was used to compare the parameters between the convex and concave side of the curve for each group.

**Results:** Hand-eye coordination and throwing accuracy was significantly worse in thoracic curve pattern group than lumbar ones for both convex and concave sides of the curve. There was no difference between curve patterns in terms of hand dexterity, hand reaction time and upper extremity stability. When compared with concave side, hand dexterity was greater in the convex side for thoracic curves (p<.05). For double curves, convex side had better hand dexterity and reaction time than concave side (p<.05). But there was no difference between convex and concave side for thoracolumbar and lumbar curve patterns (p>.05).

**Conclusions:** This study showed that hand function is affected, depending on the curve pattern in idiopathic scoliosis. There is no knowledge about how hand function is affected in patients with scoliosis in the literature. Further research following these findings may lead to an understanding of the change in hand functions and its relation with scoliosis-related characteristics, such as age, curve magnitude and trunk deformation.

**EFFECT OF PERINEURAL INJECTION THERAPY IN MODERATE AND SEVERE KNEE OSTEOARTHRITIS; A COMPARATIVE STUDY**

M. H. Abu-Zaid1, S. A. Tabra1, S. Elmorsy1. 1Rheumatology, Faculty of Medicine Tanta University Egypt, Tanta, Egypt

**Background:** Osteoarthritis (OA) is the most common rheumatologic disease. Knee OA is the most common form of symptomatic OA. It is the fourth most important global cause of disability in women and the eighth most important cause in men.

Studies found that subcutaneous prolotherapy is an effective treatment for several painful conditions. Some authors hypothesizes that subcutaneous prolotherapy injections induce apoptosis of proliferating peptidergic nociceffectors and neovessels by reducing vascular endothelial growth factor levels and restoring effective repair processes, with reduction of pain.

**Objectives:** To assess the effectiveness of perineural injection therapy as a new modality in management of pain, physical function, ambulation activity, disability and psychological status in moderate and severe knee osteoarthritis.

**Methods:** In this study, we selected 100 patients with moderate and severe knee osteoarthritis diagnosed clinically and radiologically by plain x-ray. Patients were classified into four equal groups (25 patients in each group). Group I received 6 weekly subcutaneous injections of 0.5–1 ml of buffered dextrose 5% in each chronic constriction injury points and tender points around knee. Group II received therapeutic continuous US three times weekly for 6 weeks using 1-MHz US head, set to an intensity of 1 W/cm2 for 10 min. Group III received combined perineural and US therapy. Group IV received sham US. All patients received 15 min of therapeutic continuous US three times weekly for 6 weeks using 1-MHz US head, set to an intensity of 1 W/cm2 for 10 min. Group III received combined perineural and US therapy. Group IV received sham US. All patients received 15 min of

Assessments were performed at baseline, at the end of the treatment and after three and six months. using the following measurements: Primary outcome was pain on movement assessed by visual analog scale (VAS). Secondary outcomes consisted of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores, 50 meters walking time, Lequesne index, Hospital Anxiety and Depression Scale (HADS).

**Results:** No baseline differences existed between all groups. The improvement in group IV was non-significant (p>0.05), while there was significant improvement in all other groups (p<0.05) in all primary and secondary outcomes after treatment, 3 and 6 months later. In comparing groups I, II, III the best improvement was in...
