Innate immunity in rheumatic diseases

**MECHANISM AND SIGNIFICANCE OF COMPLEMENT C3 RECEPTOR IN COLLAGEN-INDUCED RHEUMATOID ARTHRITIS MICE MODEL**

L. Dan¹, L. Ke². ¹Department of Rheumatology and Immunology, Xi'an No. 5 Hospital, ²Core Research Laboratory, the Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

**Background:** Rheumatoid arthritis (RA) is a kind of chronic autoimmune disease, mainly manifested as small joint synovitis. Disease progression appears joint swelling, bone and cartilage damage, deformity and activity limitation. The etiology of RA is still unclear and is generally considered to be an immune-mediated inflammatory disease. The activation pathway and regulation function of the complement system have become the hotspot of the research of RA pathogenesis. Previous studies have shown that C3a-/- mice had lower levels of antibodies to collagen in the Type II collagen-induced rheumatoid arthritis (CIA model), and the molecular mechanism is unclear. The small fragment C3a and large segment iC3b produced by C3 activation are the main effect products, and their biological effects are performed by combining with the specific receptor, C3aR and CD11b respectively.

**Objectives:** To investigate the mechanism of C3a and C3b, the cleavage products of complement C3 in rheumatoid arthritis, binding to their corresponding receptors, the signalling pathway of complement activation and the effect on arthritis conditions.

**Methods:** This study was intended to establish a CIA model on C3aR knockout and CR3 knockout mice (C3aR-/-or CD11b-/-) to investigate the effect of complement C3a-C3aR signalling and iC3b-CR3 signalling on rheumatoid arthritis. Methods using C57BL/6 background transgenic mice (Gifted by King's College London), Mice were divided into 3 groups according to the experimental mouse strains: C3aR-/- group, CD11b-/- group and WT control group. The clinical score of the joints in each group was measured after the establishment of the CIA model through collagen induction. Moreover, joint specimens were collected for pathology grading. Besides, the level of CD4+ T cell, CD8+ T cell, Th17/Treg ratio and the level of IFN-gamma of NK cell in mouse spleen were detected by flow cytometry.

**Results:** The clinical score of C3aR-/- group was slightly lower than that of WT group, and the clinical score of CD11b-/- group was significantly higher than that of WT group; 2. Pathological score (12 points): The CIA scores of CD11b-/- group, C3aR-/- group and WT group were 9.35±0.75, 4.81±0.63 and 5.85±0.55 respectively. The CIA scores of CD11b-/- group was significantly higher than that of WT group, which were consistent with clinical score; 3. Through the flow cytometry detection, compared with the WT group, CD4+ T cell, CD8+ T cell and Th17/Treg percentage increased significantly, and Treg cell decreased. In addition, the secretion of IFN-gamma of Splenic NK cell was significantly reduced.

**Conclusions:** IC3b as well as C3a could bind to their respective complement receptor, and express different influence in the immune mechanism of RA. The iC3b-CD11b signalling has a protective effect in RA, while the C3a-C3aR signalling has an inflammatory aggravation effect. Through this study, it helps us to invent the drug related to complement components and their receptors, and further be used in the clinical treatment of RA.

**Background:** Dendritic cells (DCs) direct the immune response against pathogens while maintaining self-tolerance by inactivating T cells in lymphoid organs and peripheral tissues. However, their aberrant activation can lead to chronic inflammation and autoimmunity. Based on the distinct transcriptional, function and distribution, DCs can be broadly categorised as plasmacytoid and myeloid (conventional) DCs. Based on recent single cell sequencing and secretome data, can be divided into CD14+ DCs (DC1), CD2_A (DC2) defined as "CD1c+CD32B+CD36+CD163+" and DC2_B (DC3) defined as "CD1c+CD32B-CD36+CD163+". In addition, populations of CD1c+CD141+ CD161+ have been described, which were known as "monocyte-like" and inflammatory DC (mDC). Most to date studies on Rheumatoid Arthritis patients investigated DCs in circulation or in synovial fluid (SF). This provided important insight into epigenetic changes in DC precursors before they enter synovial tissue, e.g. RA blood CD1c+have deregulated microRNA-34a driven epigenetic control of anti-inflammatory Axl pathway or into the influence of inflammatory milieu on DCs, respectively. However, neither (peripheral blood) PB nor SF are major sites for DC regulated T/B cell activation; instead, DCs control immune responses in the appropriate structures of lymph organs and tissues.

**Objectives:** In this study, we sought to investigate myeloid DCs in synovial tissue with the prospect of better understanding their role in driving autoimmunity in RA.

**Methods:** We developed a flow cytometry sorting strategy to characterise the phenotype of distinct myeloid DC subsets in multiple biological compartments (PB, SF and synovial tissue). Synovial tissue (ST) biopsies (RA n=9; Psoriatic arthritis n=15; Healthy donors n=12), and SF DC (n=3) were used as comparators. Synovial tissue, SF and PB DCs were sorted and microarray analysis, pro-inflammatory and regulatory cytokine expression analysis by amplified qPCR. In addition, DCs were mapped in synovial tissue in RA (n=8), PsA (n=7) and control non-inflammatory OA (n=5) by immunohistochemistry.
