Elephant in the room

We read with interest the article by Aggarwal *et al* on repository corticotropin injection (RCI) in the treatment of refractory polymyositis and dermatomyositis (PM and DM) published in the *Annals of the Rheumatic Diseases*.¹

The authors, who are well-respected researchers in the field of myositis, have done a good job in conducting a small open-label trial of RCI in the treatment of PM/DM using validated disease activity measures and outcome measures. Whether these patients were truly 'resistant' is debatable, since only 3 of the 11 patients were treated with intravenous immunoglobulin (IVIG) before entering the study. Also, three serious adverse events related to the study drug among 10 patients in a 6-month period (all requiring hospitalisation, one being disseminated zoster with pneumonitis and not counting patients with incident hypertension and hyperglycaemia) should be a major cause of concern and would invalidate their assertive statement 'RCI was generally well tolerated with a reasonable safety profile'. They have mostly toned down the efficacy conclusions drawn from their case series, although 'promotional' language creeps in at some places, such as '.....support the concept of RCI as a novel immunomodulatory therapy for myositis beyond the steroidogenesis effect.'

It is telling that we are still publishing and reading 'case reports' on the only Food and Drug Administration (FDA)-approved therapy for the treatment of PM and DM. It is also a sad reflection on an 'approved drug' that was never held to the same standards of showing efficacy and safety in prospective, double-blind, placebo-controlled trials that other drugs have to go through. The authors call it a 'proof-of-concept' study, which is an odd statement given RCI is FDA approved and marketed to treat PM/DM and then state that this is 'the first clinical trial of RCI in adult DM & PM using rigorous methodology', which nullifies previously published case studies, which form the so-called 'evidence' for the use of RCI for myositis.

Unfortunately, the authors do not mention the 'elephant in the room', which is the outrageous price of this treatment. At its current wholesale acquisition cost of \$36 382 per 400 unit 5 mL vial, a 24-week course of RCI therapy at 80 units twice a week as given in their study would require 10 vials and cost \$363 820. Although the authors of this manuscript have nothing to do with the pricing decisions related to RCI, and they do suggest a cost-benefit analysis, we recommend

readers to take into account the excessive costs of RCI before considering this treatment for their patients with inflammatory myositis.
