Juvenile recurrent parotitis (JRP) is the second most common childhood disease of the salivary glands after mumps and mainly affects children between the ages of 3 and 6. There is a male predilection, often with spontaneous resolution at puberty. However, in some cases, it can be the first manifestation of a rheumatic immune-mediated disease.

Objectives: To analyze the clinical, laboratory and imaging profile of children with JRP and investigate the prevalence of rheumatic immune-mediated diseases in these patients.

Methods: Retrospective study from 2008 to 2018 including all cases of recurrent parotitis with juvenile onset at our center. Parameters evaluated included gender, age, laterality, number of recurrences, symptoms of presentation, associated conditions, imaging details, blood tests, treatment, outcome and follow-up.

Results: 40 patients were identified over a 10-year period, with a female to male ratio of 5:3. 62.5% females. The youngest child was nine months old and the eldest was 16 years old with median age at presentation of 5 years. The median (min-max) follow-up period was 3 (0.04-33) years. 29 children (72.5%) only ever reported unilateral symptoms, while the rest had both glands affected, although not usually at the same time. Pain and swelling were the most common presenting symptoms, seen in all cases. Fever in 15 (37.5%) and whitish discharge from Stenson’s duct in 10, CT in 4, scintigraphy in 2 and biopsy of minor salivary glands in 1.

Intraglandular lymph nodes and enlarged gland. MRI was performed in 10 cases: the Juvenile Arthritis Multidimensional Assessment Report. J Reumatol 2017; 69:677-86.

SAT0501 THE IMPACT OF MORNING STIFFNESS ON THE DEFINITION OF INACTIVE DISEASE IN JUVENILE IDIOPATHIC ARTHRITIS

Maria Francesca Gigioni1, Gabriella Giancane2, Alessandra Alongi2, Silvia Rosina3, Jessica Tibaldi4, Marta Mazzoni2, Angelo Ravelli4, Alessandro Consolaro5. 1Università degli Studi della Campania L. Vanvitelli, Naples, Italy; 2IRCCS Gaslini, Genova, Italy

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. Morning stiffness is a major symptom of JIA, and is usually associated with active disease. The 2004 preliminary criteria for inactive disease (ID) in JIA did not include the assessment of morning stiffness, whereas the 2011 revision of the criteria has allowed the presence of morning stiffness (MS) lasting ≤15 minutes. MS was included in 2011 revision based on the consideration that MS of a short duration (i.e. ≤15 minutes) can represent residua of previously active disease without current active disease. However, it is unclear whether the disease status of children with ID who have or do not have morning stiffness is comparable.

Objectives: To compare the disease status of children with JIA who met the 2004 and 2011 revised criteria for ID in relation to the presence or absence of morning stiffness.

Methods: A database of 1208 Italian children included in 2 multicenter studies (1,2) who underwent a total of 3380 visits was examined to identify all visits in which the patients fulfilled the 2004 or 2011 criteria for ID. In case a patient met the ID criteria in more than 1 visit, only the first visit was retained. For each visit with ID, the duration of morning stiffness was categorized as ≤15 min or >15 min. Clinical assessments included demographic features and parent-reported outcomes.

Results: A total of 668 visits in which patients met the criteria for ID were identified. Absence of morning stiffness was reported in 564 (84.4%) visits, whereas in 104 visits (15.5%) there was morning stiffness. Among the visits with morning stiffness, in 55 (8.2%) duration was ≤15 min, and in 49 (7.3%) duration was >15 min. The table shows the comparison of disease duration and parent-reported outcomes between patients with presence or absence of morning stiffness.

Median [IQR] disease duration

JAFS total score > 0 107 (19.0) 24 (43.6) 38 (77.6) 0.001
PRQL PhS > 1 SD 61 (10.9) 22 (40.7) 38 (79.2) 0.001
PRQL Ps > 1 SD 32 (5.8) 9 (17.0) 16 (33.3) 0.001
VAS DA = 0 170 (30.1) 44 (80.0) 43 (87.8) 0.001
VAS well-being = 0 211 (37.4) 42 (76.4) 44 (88.9) 0.001
VAS pain = 0 140 (24.8) 484 39 (70.9) 31 35 (71.4) 0.001
Remission (87.5) (59.6) (41.7) < 0.001

MS: morning stiffness; IQR: interquartile range, *above the mean of healthy children (2).

Conclusion: Among patients who met the 2011 criteria for ID, those with morning stiffness ≤15 min had worse parent-reported outcomes than those without morning stiffness. This finding suggests that parents may not perceive their child’s disease state as true remission when lower degrees of morning stiffness are present. Notably, a sizeable proportion (7.3%) of children meeting the 2004 ID criteria had morning stiffness lasting >15 min. The removal of the criterion “Duration of morning stiffness of ≤15 minutes” to “Absence of morning stiffness” in the definition for ID should be considered.
