beneficial in the treatment of degenerative musculoskeletal problems. The purpose of this study is to evaluate PRP treatment efficacy on degenerated cartilage. Objectives: In this study, we aimed to determine the efficacy of platelet-rich plasma (PRP) on mechanically damaged chondrocyte cells by using different dose, different duration of exposure and different methods of activation of platelet.

Methods: Human source chondrocytes (CHON-011 ATTCC RCL-2846) were used in this study. Chondrocyte cells were produced in appropriate medium and an experimental cartilage model was created. The platelet-rich plasma was produced from platelets obtained by apheresis in the laboratory, from blood of volunteer. The platelet-rich plasma was adjusted at five different doses as 4,8x10^6, 2,4x10^6, 1,2x10^6, 6x10^5, 3x10^5. The first group of platelet rich plasma was left intact, the second group was detonated within seven minutes by applying ultrasound waves in water, the third group was activated with calcium chloride and the fourth group was determined as control group. Using a ten microliter pipette tip, a linear damage to the experimental sides was created at the widest part of the well. Cell migration was monitored at 0-4-8-24 and 48 hours at x10 magnification by in vitro microscopy and wound healing was evaluated by photographing. Migration intervals were determined quantitatively using the program named Image J.

Results: When the rates of recovery were compared to the groups, no significant improvement was observed in the intact and detonated platelet groups at 4-8 and 24 hours compared to the control group. In the third group which was activated with calcium, no significant improvement was observed in all doses at 4 and 8 hours compared to the control group. However, at the 48th hours there was a significant improvement in the doses of 1.2x10^6, 2.4x10^6 and 4.8x10^6 compared to the control group (p <0.0001). There were significant differences in intact and detonated platelets at 3x10^5 and 6x10^5 doses at 48th hours compared to control group (p <0.0001). Significant improvement was observed in all groups at levels of 1.2x10^6 and a bove (p <0.0001). When evaluated in terms of activation, there was a significant improvement in the exploded and intact groups at the 48th hour, compared to the calcium-activated group at doses of 3x10^5 and 6x10^5 (p <0.01).

Conclusion: Cartilage damage is the main pathology in the pathogenesis of osteoarthritis. All doses of PRP used in the study contributed to improvement. Meanwhile, the most critical parameter for platelet migration was timing and significant improvement was started after 48 hours.

S-ALLYL-L-CYSTEINE ATTENUATES INFLAMMATION RELATED OXIDATIVE STRESS PARAMETERS AND INCREASES ADHESION CAPACITY OF PRIMARY HUMAN OSTEOARTHRITIC CARTILAGE CHONDROCYTES

Zubevir Elmasoglu1, Zehra Aydin Bek1, Berivan Bilik2, Cem Nuri Aktekin4, Mehmet Ersin Tercan5, Cimen Karasu1, 1Gazi University Faculty of Medicine, Cellular Stress Response and Signal Transduction Research Laboratory, Department of Medical Pharmacology, Ankara, Turkey; 2Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; 3Baskent University, Rheumatology, Ankara, Turkey; 4Kartal Dr. Lutfi Kirdar Training and Research Hospital, Rheumatology, Istanbul, Turkey

Background: Osteoarthritis (OA) is characterized by progressive destruction of the articular cartilage, and chondrocytes, the only cells in articular cartilage, are in charge of maintaining the homeostasis of articular cartilage via modulating extracellular matrix anabolism and catabolism. Due to the association of the degree of oxidative degeneration of chondrocytes and OA, preventing impaired redox signaling and oxidative death of chondrocyte are suggested as potential targets to relieve OA[2]. In this respect, some photochemicals have been shown to be potential agents for preventing or treating OA due to their antioxidant and anti-inflammatory properties.[3].

Objectives: We studied the effects of an antioxidant S-allyl-cysteine (SAC), a major sulphur-containing amino acid compound of garlic[4], on the redox system, and its associations with the proliferation rate and index of human OA chondrocytes(CAcs).

Methods: Chondrocytes were isolated from the joint cartilages of OA patients (grade 4, meanage= 66 years, BMI= 29.7 ± 4.4 kg/m²). The alterations in cell proliferation (MTT), adhesion profile (RTCA-iCELLigence System), reactive oxygen species generation (ROS), lipid hydroperoxide levels (LPO), HNE-protein adduct levels (HNE), AGE-protein adduct levels(AGE), 3-nitrotyrosine levels (3-NT),

CHANGES IN THE MIRNA PROFILE AND HYPOXIC BEHAVIOUR OF HUMAN CHONDROCYTES BY THERAPEUTIC NUCLEAR MAGNETIC RESONANCE THERAPY (NMRT)

Birgit Lohberger1, Lukas Weigl2, Nicole Stuendl2, Anda Mann2, Andreas Leithner1, 1Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Groebming, Austria; 2Gazi University Faculty of Medicine, Medical Pharmacology, Ankara, Turkey

Background: Chondrocytes were isolated from the joint cartilages of OA patients (grade 4, meanage= 66 years, BMI= 29.7 ± 4.4 kg/m²). The alterations in cell proliferation (MTT), adhesion profile (RTCA-iCELLigence System), reactive oxygen species generation (ROS), lipid hydroperoxide levels (LPO), HNE-protein adduct levels (HNE), AGE-protein adduct levels(AGE), 3-nitrotyrosine levels (3-NT),
glutathione peroxidase activity (GPx), and inflammatory progenitors ICE/caspase-1 (ELISA) were determined.

**Results:** SAC increased OAC’s proliferation rate and adhesion profile at relatively low concentrations (1, 10 and 100 nM), but inhibited at higher concentrations (1-100 μM). SAC (1 nM-10 μM) inhibited ROS, LPO, HNE, AGE, and AGE-modified proteins levels. SAC increased GPx but drastically down regulated ICE/caspase-1, indicating a potential redox regulating and anti-inflammatory effect.

**Conclusion:** Results suggest that SAC has favourable effects on OA chondrocytes through protecting proliferation capacity and ameliorating redox-mediated inflammatory pathways. Further studies are needed to investigate its therapeutic potential in patients with OA.

**AB0108 THE ROLE OF CD70 IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS**

Su-Jin Yoo, Seo Wook Kang, Jinhyun Kim, Seo Joo Yoo, Chan Keol Park, Ha-Reum Lee. Chungnam National University Hospital, Rheumatology division, Dept. of Int. Med., Daejeon, Korea, Rep. of (South Korea)

**Background:** Rheumatoid arthritis (RA) is characterized by inflammation and cellular proliferation in the synovium. Activated lymphocytes and proinflammatory molecules are important in the pathogenesis of RA. CD70 belongs to the tumor necrosis factor (TNF) ligand superfamily and is typically present on activated B and T lymphocytes, natural killer cells and mature dendritic cells.

CD70 expressing CD4+ T cells are enriched in the peripheral blood and synovial fluid of patients with RA and promote autoimmunity via co-stimulatory CD70-CD27 interaction.

CD70 expression is associated with aggressive phenotype of cancer cells and it is mediated by hypoxia inducible factor 2α (HIF-2α).

**Objectives:** In this study, we examined the presence of CD70 on the surface of fibroblast-like synoviocyte (FLS) of patients with RA (RA-FLS) and investigate the role of CD70 in the pathogenesis of RA associated with HIF-2α.

**Methods:** RA FLS were obtained from 7 patients with RA who were undergone operation like total knee replacement or synovectomy. All patients were fulfilled the 2010 ACR-EULAR classification criteria for RA.

CD70 and HIF-2α messenger ribonucleic acid (mRNA) were analyzed in RA-FLS by quantitative polymerase chain reaction (qPCR).

**CD70 and CD27 on the surface of RA-FLS were stained by PE-Anti CD70 antibody and PerCP-Cy5.5-CD27 antibody respectively and evaluated by flow cytometry.**

Same experiments were performed after treatment with interleukin (IL)-17, TNF-α and HIF-2α blocking antibody (Anti HIF-2α antibody).

**Results:** CD70 and HIF-2α mRNA in the RA-FLS were elevated after treatment with IL-17 and TNF-α (Figure 1, 2). The level of CD70 expression on the surface of RA-FLS was elevated after stimulation with IL-17 and TNF-α (Figure 3). And it was lowered after treatment with HIF-2α blocking antibody as dose dependent pattern (Figure 3). CD27 wasn’t present on the surface of RA-FLS (Figure 4).

**Conclusion:** We identified the expression of CD70 on the surface of RA-FLS. And in inflammatory conditions like stimulation with IL-17 and TNF-α, both CD70 and HIF-2α mRNA were increased. The level of CD70 on the surface of RA-FLS also elevated by treatment with IL-17 and TNF-α.

The result of decreased level of CD70 after treatment with anti HIF-2α antibody suggest that CD70 expression on the surface of RA-FLS is associated with HIF-2α.

From these results, we expect that CD70-targeted therapy associated with HIF-2α may be effective for treatment with RA.
