**Background:** Myokines, such as irisin and myostatin, are cytokines and growth factors mainly expressed in skeletal muscle, which is also their primary target tissue. They are released into circulation and exert a variety of systemic effects promoting crosstalk among different tissues [1]. Irisin is known to retrieve disuse-induced bone loss by stimulating the osteoblast pathways, while myostatin was demonstrated to be highly expressed in the synovial tissues of rheumatoid arthritis (RA) subjects, with direct role in osteoclastogenesis [2, 3].

**Objectives:** To investigate whether myokines serum levels can predict one-year radiographic progression in patients with RA.

**Methods:** Forty female patients with RA, according to ACR/EULAR 2010 classification criteria, were included in the study. Blood samples were collected, and ELISA was used to measure serum levels of irisin and myostatin. Radiographs of hands and feet, taken within three months of the blood collection and a year later, were evaluated using the Sharp-van der Heijde (SvH) score to verify the one-year radiographic progression. The RA activity was assessed by disease activity score based on evaluation of 28 joints (DAS28-ESR). Statistical analysis included Mann-Whitney U test and Spearman correlation. A value of p < 0.05 was considered significant.

**Results:** The mean age of RA patients was 53 years old, mean DAS28-ESR was 4.09, mean disease duration was 11.2 years and mean BMI was 27.33 kg/m². The mean serum levels of irisin and myostatin were respectively 25.61 ± 8.25 ng/ml and 301.28 ± 1271.11 pg/ml. Considering radiographic progression, the mean values of SvH score were 28.3 and 31.3 in the baseline and after one year, respectively, resulting in a mean ΔSvH of 3. Over one year, 89.2% of the patients presented radiographic progression (ΔSvH score >0), and 10.8% presented rapid progression (ΔSvH score >5).

**Conclusion:** The serum levels of irisin and myostatin were not correlated with one-year radiographic progression. There was a tendency of increased myostatin levels in patients with rapid progression compared to patients with no progression. More studies are needed to investigate whether the myokine levels in the joint environment differ from the circulating concentration.

**AB0136 EVALUATION OF ANALGESIC ACTIVITY OF ALLOPURINOL AND FEBUXOSTAT IN EXPERIMENTAL ANALGESIC MODELS IN MICE**

S Pal, SFCCP, Meerut, India

**Background:** Allopurinol and febuxostat are xanthine oxidase inhibitor which are used in the treatment of hyperuricemia and gout. Pain is one of the important symptoms in gout patients.

**Objectives:** The present study is to evaluate the analgesic activity of allopurinol and febuxostat in two analgesic models in mice.

**Methods:** The analgesic activity of allopurinol (39 mg/kg) and febuxostat (15.6 mg/kg) was evaluated by using central analgesic model of Edy’s hot plate and peripheral analgesic model of acetic acid induced writhing. Both drugs were compared with the positive control, pentazocin for hot plate method & aspirin for the writhing method. Also both allopurinol and febuxostat were compared with each other.

**Results:** Both allopurinol and febuxostat showed significant increase in reaction time at various time periods in hot plate method & also showed significant delay in onset of writhing as well as decrease in number of writhes in writhing method. As compared to positive control result allopurinol and febuxostat result were lower. Febuxostat shows better analgesic activity as compared to that of allopurinol.

**Conclusion:** Allopurinol and febuxostat exhibited analgesic activity in both central and peripheral models of pain.

**Disclosure of Interests:** None declared.

**AB0137 ROLE OF VIMENTIN AS A TARGET OF ANTIBODIES AGAINST CARBAMYLATED PROTEINS IN RHEUMATOID ARTHRITIS PATIENTS**

Arif Pecani, Tania Colasaniti, Cristiano Alessandri, Martina Leopizzi, Riccardo Mancini, Fabrizio Conti, Guido Valesini, Francesca Romana Spinelli, Rheumatology Unit, Department of Internal Medicine, University Hospital “Sandro Pertini,” Tirana, Albania; Rheumatology Unit, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Policlinico Umberto I, Rome, Italy

**Background:** Patients with Rheumatoid Arthritis (RA) have an increased risk of cardiovascular diseases (CVD). Inflammation and autoantibodies independently promote endothelial dysfunction, which is the earliest, reversible stage of atherosclerosis. In vitro studies have demonstrated that antibodies against carbamylated proteins (anti-CarP), recently described in RA patients, can induce the production of proatherosclerotic molecules like Vascular Cell Adhesion Molecule (VCAM-1) and activate Interleukin-1 Receptor-Associated Kinase (IRAK-1), Nuclear Factor kB (NF-kB), inducible Nitric Oxide Synthase (iNOS) in endothelial cells (1,2). Moreover, anti-CarP are associated to endothelial dysfunction and subclinical atherosclerosis in RA patients (3).

**Objectives:** Aims of the present study were: 1) to analyze the role of vimentin as a target of autoantibody response in the serum of patients with RA and 2) to investigate the expression of vimentin and carbamylated proteins in endothelial cells.

**Methods:** Consecutive RA patients were enrolled in this study. Vimentin was carbamylated and used as an antigen for the detection of anti-Vimentin Carbamylated antibodies (CarVim), through immunoenzymatic methods. Cells were incubated with anti-vimentin and carbamylated antibodies. The presence of vimentin and carbamylated proteins was investigated by immunofluorescence on the immortalized endothelial cell line EA.hy 926.

**Results:** Eighty-eight (88) RA patients were enrolled in this study. Vimentin was carbamylated and used as an antigen for the detection of anti-Vimentin Carbamylated antibodies (CarVim), through immunoenzymatic methods. Cells were incubated with anti-vimentin and carbamylated antibodies. The presence of vimentin and carbamylated proteins was investigated by immunofluorescence on the immortalized endothelial cell line EA.hy 926.
