QUALITY OF LIFE AND TREATMENT SATISFACTION IN CHINESE PATIENTS WITH CHRONIC KNEE OSTEOARTHRITIS PAIN: A CROSS-SECTIONAL STUDY

Qingyun Xue1, Hubin Long2, Jianhao Lin1, Dongping Du2, Jin Zhou3, Jinwei Chen1, Li Shu1, Yanlei Zhang3, Yan Cheng3, MA Xiao4, Zhi Zhang4, 1Beijing Hospital, Department of Orthopedics, Beijing, China; 2Peking University People’s Hospital, Arthritis Clinic and Research Center, Beijing, China; 3Shanghai Jiao Tong University Affiliated Sixth People’s Hospital, Department of Pain Management, Shanghai, China; 4The Second Xiangya Hospital of Central South University, Department of Rheumatology and Immunology, Changsha, China; 5Eli Lilly and Company, Shanghai, China; 6The First Affiliated Hospital of Harbin Medical University, Department of Rheumatology and Immunology, Harbin, China

Background: Joint pain is one of the most common symptoms of osteoarthritis (OA) and affects the physical function and quality of life of patients. Objectives: To determine the impact of chronic pain due to knee OA on health-related quality of life (HRQoL) and evaluate treatment satisfaction of current medications among Chinese patients. Methods: A cross-sectional survey was conducted in orthopedics, rheumatology and pain departments in five first-class hospitals in China from March to October 2018. Eligible patients were ≥40 years old, with diagnosed knee OA, experiencing joint pain for at least 3 months and receiving oral medications during the past 12 months. Socio-demographics, disease characteristics, Brief Pain Inventory (BPI), treatment information, Treatment Satisfaction Questionnaire for Medication (TSQM-1-4), and HRQoL (EQ-5D-5L) were assessed. Descriptive analysis and t-test were used for statistical analysis. Results: A total of 601 patients were included and 75.2% of them were female. The mean (SD) age was 61.77 (9.53) years. More than half (55.1%) had at least 1 comorbidity. The most common comorbidities were hypertension (39.6%), diabetes (15.3%), gastritis (14.3%) and coronary heart disease (12.5%). The mean (SD) age at first diagnosis of knee OA was 58.13 (9.62) years. The most commonly used current treatments for knee OA were oral medication (78.0%), followed by patch or ointment (45.1%) and intra-articular hyaluronic acid injection (31.5%). The mean (SD) of BPI-Severity and BPI-Interference ratings were 3.78 (1.62) and 2.97 (1.70), respectively. More than half (52.9%) of patients rated BPI-average pain <4 (0.62 vs 0.84, p<0.0001). The mean (SD) scores of TSQM effectiveness, side effects, convenience and global satisfaction were 54.19 (14.13), 96.00 (10.93), 62.30 (10.42) and 58.97 (15.43), respectively. The scores in all of the four dimensions of TSQM were lower in patients with BPI-average pain ≥4 than in those with BPI-average pain <4 (effective- ness: 51.01 vs 57.81, p=0.0001; side effects: 94.91 vs 97.24, p=0.0099; convenience: 60.18 vs 64.71, p=0.0001; global satisfaction: 57.74 vs 60.35, p=0.0402). Conclusion: Chronic pain due to knee OA, especially moderate to severe pain, has significant impact on patients’ HRQoL and work productivity. Patients were not satisfied with current treatments. There are unmet needs for better pain management including more drug choices in China to improve the treatment satisfaction. Osteoporosis

CAN STATINES IMPROVE BONE QUALITY IN POSTMENOPAUSAL OSTEOARTHRITIS? OROSTEOSOROSIS?

Pablo Astesana1, Paula Alba2, Carla Gobbi2, Ruth Fernandez3, Eduardo Albiero3, Marcelo Yorio2.1Universidad Nacional de Córdoba, Córdoba, Argentina; 2Universidad Nacional de Córdoba, Córdoba, Argentina; 3Imibic, Córdoba, Spain

Background: Osteoporosis (OP) is the most frequent metabolic bone disease. It has low bone mass and microarchitectural deterioration, which increases the risk of fractures. The most commonly used drugs are bisphosphonates, however statins (ST) have pleiotropic properties, and some researchers suggested their use in OP. Objectives: To determine the effect of ST on bone mineral density (BMD) in postmenopausal osteoporotic women. Methods: A cross-sectional study, control case where postmenopausal women with hypercholesterolemia treated with ST for a period not less than 6 months were studied for two years. The control group was post- menopausal population that did not receive statins. Exclusion criteria: Diabetes, previous treatment with estrogen, calcitonin, anabolic, steroids, bisphosphonates or vitamin D during a period of 6 months prior to enter to the study or with amenorrhea less than 12 months. We evaluated age, weight, height, BMI, personal and first degree family members’ history of fracture, use of corticosteroids, smoking, alcoholism, daily calcium intake, sedentary lifestyle, phosphocalcic metabolism laboratory and Vitamin D. All patients were performed Bone Densitometry by dual-energy X-ray absorptiometry (DXA) with an Hologic equipment in right hip and lumbar spine, staging them according to WHO. The statistical analysis was performed using the Student’s test and the Fisher test for categorical variables. Values of p less than 0.05 were considered significant.

Results: 202 patients were enrolled in the ST group and 203 in the control group. Age, weight, height and BMI were 62.54; 69.6; 1.60 and 27.1 in the ST group and 58.5; 65.7; 1.59 and 26.83 in the control group respectively (p = 0.000, p = 0.001 p = 0.79, p = 0.38). There were no significant differences in risk factors for OP between groups. The average lumbar BMD was -0.87 for the ST group and -1.76 for the control group (p = 0.000), the average femur neck BMD was -1.15 for the ST group and -1.56 for control (p = 0.000), the total hip BMD was -0.32 for the ST group and -0.74 for the control group (p = 0.001), vitamin D was 25.57 for the ST group and 27.71 (p = 0.120).

Conclusion: ST can improve Bone Mineral Density in postmenopausal women, more studies are needed to confirm these results.

INCIDENCE OF FACTORS AND ASSOCIATED RISK FACTORS DURING THE DRUG HOLIDAYS PERIOD WITH BISPHOSPHONATES

Laura Bautista1, Angel Delgado Zamorano2, Asunción Salmeron2, Intramadilla Gómez Gracia1, Ladehesa Pineda Lourdes1, Pérez Sánchez Laura1, Gómez García Ignacio1, Font Ugarte Pilar2,3, María del Carmen Castro Villegas2,3, Alejandro Escudero Contreras2,3, Eduardo Collantes Estevez2,3, Reina Sofia University Hospital; Rheumatology, Cordoba, Spain; 2University of Cordoba, Cordoba, Spain; 3IMIBIC, Cordoba, Spain

Background: Biphosphonates are the most widely used treatment for osteoporosis. The optimal treatment duration, however, remains unclear. The occurrence of adverse effects, such as osteonecrosis of the jaw (ONJ) and atypical femoral fractures (AFF), has raised the issue of discontinuation (‘drug holiday’) after a certain treatment period. Objectives: To assess the incidence of fractures in patients during the drug holidays period with bisphosphonates, as well as to determine the risk factors are associated to it.

Methods: Analytical, observational, longitudinal, and ambispective study of a cohort of patients with postmenopausal osteoporosis or men over 50 years of age treated with oral bisphosphonates (at least for 5 years) or intravenous (at least for 3 years) and who had been at least for one year in a drug holidays period, from 01/01/2012 to 12/31/17. Patients treated with corticosteroids and/or with diseases with effects on bone

AB0818

INFORMATION ABOUT BISPHOSPHONATES
metabolism were excluded. Statistical analysis included a descriptive study of the variables to assess the association between the incidence of fractures and various risk factors, as well as univariate and multivariate Cox regression analysis.

Results: 128 patients with osteoporosis were studied, of which 19 (14.7%) suffered an osteoporotic fracture during the follow-up. Bivariate analysis showed in the group of patients with fractures a higher proportion of smoking patients (p = 0.004), osteopenia treatment (p = 0.005) and a femoral neck T score lower at the beginning of the drug holidays period (2.07 (0.68) vs. 1.58 (0.63), p = 0.008).

In addition, there was a higher proportion of patients with fracture with moderate risk before the start of the drug holidays period (p = 0.007). The fracture survival curves were lower in patients older than 75 years (p = 0.04). When applying the same treatment, for each year increase, the risk of fracture was increased by 6% (p = 0.04), whereas for the same age, this risk was increased 4.33 times in patients who were treated with Risedronate versus those with Alendronate (p = 0.05).

The multiple regression analysis showed that vertebral fracture was independently associated with Tabaco (HR 4.28 p=0.047).

Conclusion: Based on our results, it would be useful to follow closely those patients during drugs holidays period who are smokers, older than 75 years, with osteopening treatment, who present a low femoral neck tscore and/or have been previously treated with Risedronate.

AB0819 HANDGRIP STRENGTH PREDICTS HIGH FRACTURE RISK IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Federica Bellone1, Nunziata Morabito1, Agostino Gaudio2, Gabriella Martino1, Alberto Sardella1, Antonino Lasco1, Antonino Catalano1.

University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy; University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy

Background: Accumulating evidence has revealed that the risk of osteoporosis related fractures is significantly increased in type 2 diabetes mellitus (T2DM) patients in comparison with healthy controls. Dual X-ray Absorptiometry (DXA) derived bone mineral density (BMD) is not completely useful to discriminate at risk patients.

Objectives: To find a valuable clinical tool that is helpful to identify T2DM subjects with poor bone health, finally preventing fragility fractures.

Methods: In a setting of Caucasian subjects with T2DM, anthropometric data and information about metabolic control and diabetic complications were recorded. Handgrip strength by dynamometer, FRAX derived 10-years probability of major osteoporotic fractures and hip fractures were also assessed. Bone evaluation was performed by a dual-energy X-ray absorptiometry (DXA) densitometer at the lumbar spine (L1-L4) and at the femoral neck; based on specific software, the trabecular bone score (TBS) was calculated. Lateral scan of thoracic and lumbar spine was assessed to investigate morphometric vertebral fractures (VFs).

Results: 29 patients (female 65%) [median age 67 (60 to 70)] with T2DM were considered. Morphometric vertebral fractures were detected by DXA in 17% of patients without any gender differences (males vs. females, p=0.6). The median ten years probability of fractures was 8.1% and 2.3% as for major osteoporotic or hip fracture respectively. Median femoral neck T-score value [-1.1 SD (-1.8 to -0.5)] was indicative of a slight osteopenia while lumbar spine T-score was even in the normal range [-0.8 SD (-1.5 to -0.1)]. The median TBS value was 1.28 (1.2 to 1.31) and TBS was positively associated with BMD at lumbar spine and femoral neck. Median handgrip strength value was 22.3 kg (18.9 to 31.3). At multiple regression analysis, handgrip strength predicted both lumbar (β= 0.009, SE 0.0034, p=0.01) and femoral neck BMD values (β= 0.006, SE 0.002, p=0.001). Age (β= -0.008, SE 0.002, p=0.007) and handgrip strength (β= 0.01, SE 0.002, p=0.0001) were also independently associated with TBS score, after correcting for mean HbA1c values and time since T2DM diagnosis.

Conclusion: Handgrip strength may be a reliable tool to screen for bone fragility in T2DM.

AB0820 COGNITIVE IMPULSIVITY CORRELATES WITH BONE MINERAL DENSITY

Alberto Sardella, Federica Bellone, Carmen Giulia Lasco, Gabriella Martino, Nunziata Morabito, Antonino Catalano. University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy

Background: Cognitive impairment is known to be associated with low bone mineral density (BMD) and low levels of BMD have been associated with increased rates of progression from mild cognitive impairment to Alzheimer’s disease and with the onset of episodic verbal learning deficit.

Objectives: The potential involvement of executive functions impairment on BMD is still unclear. The aim of this study was to investigate the correlations between cognitive impairment, BMD and fall risk.

Methods: Cognitive impulsivity was measured by Stroop Color and Word Test (SCWT) administration in a setting of 40 consecutively recruited postmenopausal women referring to a outpatient clinic for the evaluation of fractures risk. SCWT is a neuropsychological test able to assess the ability to inhibit cognitive interference: during the administration, women were required to quickly read three different tables of which two represented the “congruous condition” in which participants were invited to read names of colors printed in black ink and name different color patches. In the third table, named “incongruous condition”, color-words were printed in inconsistent color ink (e.g. the word “red” is printed in green ink) and participants were required to name the color of the ink instead of reading the word. Women with Mini Mental State Examination (MMSE) score < 24, known neurologic or psychiatric disorders, history of significant hearing or visual impairment, or significant physical disability, history of uncontrolled diabetes and abnormal thyroid function, cancer, heart, respiratory, kidney or liver failure were excluded. BMD was measured at lumbar spine and femoral site by a DXA densitometer (Holoc engine Discover). History of falls in the previous 12 months was recorded.

Results: Cognitive impulsivity, as highlighted by making errors at the SCWT, was significantly associated with lumbar spine and femoral neck T-score (r = -0.39, p = 0.01 and r = -0.43, p = 0.008, respectively); MMSE score was not associated with T-score values, neither at lumbar spine (r = 0.09, p = 0.5) nor at femoral neck (r = 0.2, p = 0.21); differently MMSE score was significantly associated both with Stroop test (r = 0.34, p = 0.02) and time interferences (r = -0.39, p = 0.01). Furthermore, time interference was positively associated with the self-reported history of falls (r = 0.342, p = 0.031).

Conclusion: Cognitive impulsivity was significantly associated with BMD values and higher prevalence of falls in postmenopausal women. It could be considered as a possible clinical risk factor for osteoporotic fractures.
