Background: The abatacept global post-marketing epidemiology programme includes observational studies based on biologic disease registries and health-care claims database studies to evaluate infection and malignancy risks associated with abatacept treatment, as used in routine clinical practice.

Objectives: To assess the risk of solid tumour malignancies in patients with RA treated with abatacept vs conventional synthetic (cs)DMARDs and other biologic (b) or targeted synthetic (ts)DMARDs.

Methods: Data were analysed from four cohorts: two biologic registries (the Anti-Rheumatic Therapy in Sweden [ARTIS] register and the Rheumatoid Arthritis Observation of Biologic Therapy [RABBIT] German registry), a disease registry (FORWARD, The National Databank for Rheumatic Diseases in the USA) and a healthcare claims database (the population-based British Columbia Canadian RA Cohort [BC]). Exposure defined as "ever exposed" unless specified. Crude incidence rates (per 1000 patient-years of exposure) with 95% CIs were calculated for overall malignancy, breast cancer, lung cancer and lymphoma. Adjusted risk ratios (RRs) with 95% CIs were estimated using multivariate models adjusting for demographics, comorbidities and other potential cofounders within each database and were subsequently pooled using a random-effects model for meta-analyses.¹

Results: Patients treated with abatacept (~5100), csDMARDs (~74K) and other b/tsDMARDs (~37K) were followed up for a mean of 3.0–3.7, 3.0–6.2 and 3.0–4.7 years, respectively. Patients were mainly female (71–86%), with a mean age ranging from 55–63 years, and 4–34% had a history of malignancy. A greater number of abatacept-treated patients had been treated with ≥2 prior biologics (abatacept, 44–85%; csDMARDs, 11% [FORWARD] and other b/tsDMARDs, 0–19%). The incidence rate of overall malignancy in abatacept-treated patients was low (Table). Adjusted RRs (95% CIs) for abatacept vs csDMARDs (range: 0.8 [0.2, 3.4] to 1.3 [0.5, 3.3]; pooled estimate: 1.1 [0.8, 1.5]) and abatacept vs other b/tsDMARDs (range: 1.0 [0.4, 2.6] to 1.2 [0.6, 2.3]; pooled estimate: 1.0 [0.8, 1.3]) showed no increased risk in overall malignancy. Although individual registries showed a slight increase in breast (BC), lung (RABBIT) and lymphoma (ARTIS) cancers in patients treated with abatacept, numbers were too low to make an accurate comparative risk assessment.

Conclusion: While the development of malignancy is a potential risk associated with the use of immunomodulators, data from this large, international, post-marketing epidemiology programme suggest that the risks of overall malignancy and breast, lung or lymphoma cancers were not significantly increased in patients treated with abatacept. These data are consistent with the established safety profile of abatacept.

OP0227

EFFECTS OF SUCCESSIVE SWITCHES TO DIFFERENT BIOSIMILARS INFLIXIMAB ON IMMUNOGENICITY IN CHRONIC INFLAMMATORY DISEASES IN DAILY CLINICAL PRACTICE

Ambre Lauret¹, Anna Moltó¹, Vered Abitbol², Loriane Gutermann³, Ornella Conort³, Francois Chast³, Claire Goulvestre⁴, Claire Le Jeune⁵, Stanislas Chaussade², Christian Roux¹, Frédéric Batteux⁴, Maxime Dougados¹, Yannick Allanore¹, Jérôme Avouac¹. ¹Paris Descartes University, Cochin Hospital, Rheumatology, Paris, France; ²Paris Descartes University, Cochin Hospital, Gastroenterology, Paris, France; ³Paris Descartes University, Cochin Hospital, Pharmacy, Paris, France; ⁴Paris Descartes University, Cochin Hospital, Immunology, Paris, France; ⁵Paris Descartes University, Cochin Hospital, Internal Medicine, Paris, France

Background:

Objectives: To determine whether the successive switches from innovator infliximab to a first then a second biosimilar infliximab increase the risk of immunogenicity during a 3-year observation period.

Methods: This is a usual care study performed in Cochin Hospital, Paris, France. First switch from innovator infliximab to a first biosimilar infliximab occurred in October/December 2015 and the second switch from the first to the second biosimilar infliximab started in December 2017. The end of the observation period was December 2018. Immunogenicity was defined by the detection of positive anti-drug antibodies (ADA >10 ng/mL), at least at two consecutive time points. The primary outcome of the study was the development of immunogenicity during the observation period. Secondary outcomes were i) the point prevalence of positive ADA at baseline, ii) the influence of the successive switches to biosimilars on the risk of immunogenicity and iii) the retention rate of biosimilar infliximab at the end of the observation period.

Results: Our prospective cohort consisted on 265 patients on maintenance therapy with innovator infliximab (135 axSpA, 64 with inflammatory bowel diseases, IBD, 31 with RA, 21 with PsA, 8 with uveitis and 6 with other chronic inflammatory diseases) who switched to biosimilar infliximab. Then, 140 patients switched to the second biosimilar infliximab, 26 remained treated with the first biosimilar, and innovator infliximab was re-established in 55 patients. 29 patients (15 females, 14 males) had positive ADA at baseline (point prevalence: 12.4%), before the switch to biosimilar infliximab. Among these 29 patients, 15 had axSpA (11%), 6 RA (19%), 6 IBD (9%) and 2 PsA (10%). Among the 236 patients with no ADA at baseline, 20 patients developed ADA during the observation period, corresponding to a rate of 3 for 100 patient years. The mean time to positive ADA detection was 21.2±13.7 months. Kaplan Meyer curve showed no influence of the number of biosimilars infliximab received on immunogenicity (Figure 1A). Among the 20 patients with positive ADA, 4 were back to innovator infliximab at the time of ADA detection, 10 patients were exposed to the first biosimilar and 6 to the second. The risk of treatment discontinuation was significantly higher in patients with positive ADA at baseline or during follow-up compared to patients without ADA (Figure 1B, Hazard Ratio 2.27, 95% confidence interval 1.33-3.89). No predictive factor of immunogenicity was identified (including type of disease, age, sex, BMI or concomitant DMARD intake). The retention rate of biosimilar infliximab (Figure 1C) was 58% (154/265) at the end of observation period, including 131 patients treated with the second biosimilar and 23 who remained treated with the first biosimilar.

Conclusion: In this usual care study with a 3-year observation period, the development of immunogenicity was low (3 for 100 patient years) and not favored by the switch to biosimilars infliximab. Thus, immunogenicity does not constitute a barrier to interchangeability between biosimilars infliximab in chronic inflammatory diseases.
