syndrome n=7 (17.1%), SAVI syndrome n=3 (7.3%), CRMO n=4 (9.8%), PFPAPA n=2 (4.9%), APLAID n=1 (2.4%), Sticker syndrome n=1 (2.4%), and 3 unknown cases with genetic test negative n=3 (7.3%). Current treatment is variable among patients, 6 (15.8%) are taking disease-modifying antirheumatic drugs (DMARDs), 9 (23.7%) Colchicine, 8 (21.1%) Anakinra, 13 anti-TNF therapy (34.2%), 1 (2.6%) Ruxolitinib and 1 (2.6%) Abatacept. Only 6 patients were receiving corticoids with mean prednisone dose of 7.5 mg/day. The global ADDI mean score was 2.3 ± 2.2. Regarding the eight different items included in the item, musculoskeletal involvement was the dominant score with 0.42. The patient with APLAID syndrome had the highest score of 6 followed by BLAU syndrome with 4.71. FMF has the lowest score with 0.83. Laboratory test results were mean ESR 27.2 ± 26.7mm/h, CRP 0.7 ± 1.3 mg/dl, AP 13.9 ± 16.6mg/L. Proteinuria was present in 2 patients with mean 286.5 ± 246.1mg/mg. EM and ML applied ADDI in 5-10 minutes average.

Conclusion: ADDI is a feasible index suitable to measure damage in a single patient. Despite it was performed to the four most common AIDs it could be applied to other diseases. In our cohort the mean ADDI index was low and musculoskeletal item has the highest score. This result could be explained by the tight control of the disease and successful targeted therapy. Laboratory tests also support this finding. Nevertheless, some organ systems are not assessed like respiratory, cardiovascular or cutaneous damage, important in some syndromes. Knowing the difficulties of applying an unified index for all diseases, ADDI may be supportive in other AIDs and longitudinal cohorts.

HENOCH-SCHÖNLEIN PURPURA AND UVEITIS, AN UNUSUAL ASSOCIATION

Ilaria Maccora1, Francesca Tirelli1, Gabriele Simonini2, Teresa Giani2, Rolando Cimaz2.1Post Graduate School of Pediatrics, University of Florence, Florence, Italy; 2Pediatric rheumatology, AOI Meyer, Florence, Italy

Background: Henoch-Schönlein purpura (HSP) is the most common childhood vasculitis characterized by cutaneous palpable purpura predominantly located in the lower limbs, arthralgia/arthritis, renal and bowel involvement. To our knowledge only 4 cases of HSP with ocular involvement have been reported so far.

Objectives: We describe a 6-year-old female patient who presented HSP and panuveitis.

Methods: Describe a case report.

Results: A 6-year-old female, previously in good health, received the diagnosis of HSP for cutaneous palpable purpura on her lower limbs, bilateral ankle arthritis and haematuria. Two weeks later the girl was admitted to our Emergency Department due to monolateral ocular pain with red eye. At ophthalmological assessment there was evidence of anterior uveitis with edema and atopia of the optic disc. Blood tests showed increased values of CRP (1.92 mg/dl) and ESR (69 mm/h) with normal values of complement levels and complete blood count. Uralysis displayed mild hematuria and proteinuria. Immunoglobulin levels were slightly increased: IgG (1850 mg/dl, n.v. 540-1330 mg/dl), IgA 244 mg/dl (n.v. 50-240 mg/dl) and IgM 72 mg/dl (n.v. 50-180 mg/dl). An extensive infectious work-up for viral, bacterial and parasitic infections was negative. ANA, ANCA, ASCA, LAC, HLA B27 and B51 were all negative. Chest X ray, abdominal ultrasound and echocardiography were negative. A brain MRI with contrast revealed an iris inflammation and excluded CNS involvement. Systemic therapy was started with i.v. methylprednisolone (30mg/kg/d for 3 consecutive days) and continued with oral predni-
sone (2 mg/kg/day), with a progressive improvement of the ocular, skin, nephrological and articular involvement. Prednison was then gradually tapered over 2 months without disease recurrence.

Conclusion: In our literature search we were able to find an association between HSP and uveitis only in two adults and in an 11-year-old child. All these patients showed cutaneous and articular involvement and 3/4 nephrological involvement. Uveitis was observed in the first week of vasculitis onset. Although rare, the presence of ocular involvement can occur during HSP.

CHILDREN IN RISK OF LOW BONE MASS HAVE MORE THAN 2 RISK FACTORS

Berta Paula Masillores López1, Dacia Cordel1, Joseylen Betancourt2, Gloria Fraga3, Estefania Agueda-Masache4, Mireia López-Corbeto5, Montserrat Torrent5, Ana Maria Marin5, Silvia Herrera6, Jordi Casademont6, Hector Corominas1, Jorge Malouf1,3,4,8 Santa Creu i Sant Pau Hospital, Rheumatology, Barcelona, Spain; 2Moises Brogi Hospital, Rheumatology, Barcelona, Spain; 3Santa Creu i Sant Pau Hospital, Pediatrics, Barcelona, Spain; 4Vall d’Hebrón Hospital, Pediatric Rheumatology, Barcelona, Spain; 5Santa Creu i Sant Pau Hospital, Bone Metabolism Unit, Internal Medicine, Barcelona, Spain; 6Santa Creu i Sant Pau Hospital, Internal Medicine, Barcelona, Spain

Background: Low Bone Mass (LBM)/Infantile Osteoporosis (IOP) require an active evaluation for its diagnosis and prevention. Therefore, its inci-
dence is unknown and could be undertreated. The systematic collection of risk factors associated with LBM/IOP could help identify the population at risk of presenting it.

Objectives: To assess the prevalence and number of risk factors (RF) in the pediatric population at risk of developing LBM/IOP. Assess its influ-
ence on Bone Mineral Density.

Methods: Demographic and clinical data were prospectively collected from patients from 2 to 20 years of age, who had at least one risk factor for LBM/IOP, among them: chronic diseases, treatment with immunosuppres-
sants and/or corticosteroids and insufficient calcium intake. Calcemia, cal-
curia, and Vitamin D were determined in blood samples, and whole body and lumbar DXA were performed. The calcium intake, the number of previous fractures and otherRF were collected.

Results: Data were collected from 103 patients, with an average age of 9.8 years, 52.4% women, and 80% Caucasians. Of these, 9 were pre-
schoolers (2-3 years old), 33 schoolchildren (4-9y), 55 teenagers (10-
17y) and 6 young people (18-20y).

The most frequent diagnoses were: Malabsorption/Food allergies: 46.6%, JIA: 17.5%, Nephropathies: 17.8%, Hematological diseases: 6.8%, and Vasculitis and connective tissue diseases: 3.9% each.

The frequency of RFs can be observed in Table 1

The average dose of current corticoids was 0.21 mg/kg/day of prednison with a total cumulative average dose of: 7 gr, with an exposure of 1 to 144 months. 43% of the sample had an isolated RF, 38% had 2 RF, 31% 3, 15% 4, and 12% 5 or more. 87% of the sample presented a LBM and 4.8% met criteria for Opi for vertebral fractures, 3 of them asymptomatic and discovered by morphometry.

In the multiple linear regression analysis: age, Latin ethnicity, gender, and hypovitaminosis D were the main RFs related to lumbar BMD. Likewise,
