Background: Juvenile Idiopathic Arthritis (JIA) is a chronic childhood arthritis with onset before age of 16 and has a significant degree of morbidity that negatively affects quality of life. Uveitis, which is defined as the inflammation of the iris, ciliary body and choroid, is the most common cause of morbidity of JIA. This study was planned to collect data from a Turkish cohort to provide the initial national prevalence data of patients with JIA.

Objectives: The objective of this study was to determine the frequency of JIA subtypes in Turkey. We also aimed to assess the frequency and characteristics of eye involvement in JIA.

Methods: This national, non-interventional, multicenter, observational study was conducted in a retrospective manner in four study centers which were main referral pediatric rheumatology clinics across Turkey. Data on patient demography, medical history, JIA disease characteristics, laboratory data, cases of JIA-associated uveitis, JIA treatment history and data on other comorbidities were collected from a cohort of 500 patients.

Results: Oligoarthritis (n=194, 38.8%) was the most common JIA disease characteristic in this study cohort. The frequency of the subgroups was as follows: Enthesitis-Related Arthritis (ERA) in 23.2% (n=116), polyarthritis in 15.6% (n=78), systemic arthritis in 12.2% (n=61), psoriatic arthritis in 5.2% (n=26), idiopathic arthritis in 2.8% (n=14) and polyarthritis (RF+) in 2.2% (n=11) of patients were identified. The most frequently prescribed treatment for JIA was methotrexate (n=384, 76.8%). A total of 85 comorbidities were reported, and the most frequently reported comorbidity was Familial Mediterranean Fever (FMF) (n=63, 12.6%). The number of patients with JIA-associated uveitis diagnosis was 34 (6.8%), and the mean duration of uveitis was 3.2 (±2.3) years. The mean duration between the initial JIA diagnosis and diagnosis of uveitis was 1.8 (±1.0) years. Among 34 patients with uveitis, 45 eye involvement were identified: left eye, right eye and both eyes were affected in 5, 8 and 16 patients, respectively. Five patients (14.7%) had uveitis-related complications that required surgical intervention.

Conclusion: The main difference from the European Caucasian population is the lower frequency of oligoarticular JIA and higher frequency of ERA in Turkish JIA patients. Uveitis was also somewhat lower than expected. The main difference from the European Caucasian population was 1.8 (±1.9) years. Among 34 patients with uveitis, 45 eye involvement were identified: left eye, right eye and both eyes were affected in 5, 8 and 16 patients, respectively. Five patients (14.7%) had uveitis-related complications that required surgical intervention. The most frequently prescribed treatment for JIA was methotrexate (n=384, 76.8%). A total of 85 comorbidities were reported, and the most frequently reported comorbidity was Familial Mediterranean Fever (FMF) (n=63, 12.6%). The number of patients with JIA-associated uveitis diagnosis was 34 (6.8%), and the mean duration of uveitis was 3.2 (±2.3) years. The mean duration between the initial JIA diagnosis and diagnosis of uveitis was 1.8 (±1.0) years. Among 34 patients with uveitis, 45 eye involvement were identified: left eye, right eye and both eyes were affected in 5, 8 and 16 patients, respectively. Five patients (14.7%) had uveitis-related complications that required surgical intervention.

THE EFFECT OF INTRA-ARTICULAR STEROID INJECTION ON THE CARTILAGE THICKNESS IN JUVENILE IDIOPATHIC ARTHRITIS

Nihal Sahin1, Sumeyra Özdemir Cicek2, Ayseur Pac Kisaarslan3, Muammer Hakan Poyrazoglu4, Ruhan Düşünsel5. Erciyes University, Pediatric Rheumatology, Kayseri, Turkey

Background: Intra-articular corticosteroid injection is a choice in the treatment of juvenile idiopathic arthritis (JIA), especially in large and few joints involvement. Intra-articular steroid injection provides relief in active synovitis but its effects on cartilage are controversial.

Objectives: The aim of this study is to evaluate the effect of intra-articular steroid injection on distal femoral cartilage thickness in patients with JIA by ultrasonography.

Methods: Distal femoral cartilage thicknesses were measured before the procedure and 6 months later by ultrasonography in the patients that were injected an intra-articular steroid to the knee.

Results: The mean age of the patients was 12.1±4.8 years. Nine of patients were girls and 2 were boys. The mean disease duration was 5.1±4.2 years. Ten patients had oligoarticular JIA and one patient had enthesitis-related arthritis. The number of patients injected to the right knee was 3, the left knee was 5 and both the knee was 3. The femoral cartilage thickness before the procedure was 3.0 mm [min-max 2.0-3.65 mm], 6 months after the procedure was 2.95 mm [min-max 2.0-3.55 mm] and there was no statistical difference (p<0.05).

Conclusion: In this study, no effect of intra-articular steroid treatment on cartilage was observed. However, the number of patients is lack. Therefore, we planned a comprehensive study with more patients.

CLINICAL OUTCOMES OF ANTI-NUCLEAR ANTIBODY POSITIVENESS IN THE 0-18 AGE GROUP: SINGLE-CENTER REAL-WORLD EXPERIENCE

Nihal Sahin1, Ayseur Pac Kisaarslan2, Sumeyra Özdemir Cicek3, Neslihan Gönül2, Ayşe Seda Pinarbaşı2, Sibel Yeş2, İsmail Dursun2, Muammer Hakan Poyrazoglu3, Hüseyin Kilic3, Ruhan Düşünsel1, Erciyes University, Pediatric Rheumatology, Kayseri, Turkey; 2Erciyes University, Pediatric Nephrology, Kayseri, Turkey; 3Erciyes University, Medical Microbiology, Kayseri, Turkey

Background: Anti-nuclear antibody (ANA) assay is important in the diagnosis of autoimmune diseases. However, it has a poor positive predictive value and is detected positive in 10% of general population. In this study, the children that ANA assay was performed in a tertiary pediatric clinic, was evaluated and was aimed to investigate the clinical outcomes in positives.

Objectives: In this study, the children that ANA assay was performed in a tertiary pediatric clinic, was evaluated and was aimed to investigate the clinical outcomes in positives.

Methods: 0-18 age group patients that ANA assay was requested in the various clinics of Erciyes University were included. The patients with positive ANA assay and access to hospital records were retrospectively examined. Patients with and without autoimmunee disease were identified as group 1 and group 2, respectively.

Results: The number of patients who required ANA assay in pediatric clinics was 3812. There was a positive ANA assay in 1010 of these patients. The medical records of 909 patients were reached. There were 345 (38%) patients in group 1 and 564 (62%) in group 2. In group 1, female gender was higher compared to group 2 (p <0.05).
