CORRELATION BETWEEN SERUM RESISTIN AND CAROTID INTIMA-MEDIA THICKNESS AS A MARKER OF SUBCLINICAL ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Omnia Ahmed1, Mona Abdel Mageed2, Mohamed Baraka2, Dalia Eliein2, Ahmed Shabab3, Faculty of Medicine, Alexandria University, Rheumatology and Internal Medicine, Alexandria, Egypt; Faculty of Medicine, Alexandria University, Rheumatology and Internal Medicine, Alexandria, Egypt; Faculty of Medicine, Alexandria University, Radiodiagnosis, Alexandria, Egypt; Faculty of Medicine, Alexandria University, Chemical and Clinical Pathology, Alexandria, Egypt; Faculty of Medicine, Alexandria University, Rheumatology and Internal Medicine, Alexandria, Egypt

Background: Although SLE management has improved markedly in the last few decades, cardiovascular disease (CVD) is still one of the most important leading cause of death. Subclinical atherosclerosis is increased in patients with SLE and it is not fully explained by traditional cardiovascular risk factors. Evidences suggest that resistin is involved in pathological processes leading to CVD including; inflammation, endothelial dysfunction, thrombosis, angiogenesis and smooth muscle cell dysfunction. Objectives: to determine the relation between serum resistin level and carotid intima-media thickness by doppler technique as a marker of premature or subclinical atherosclerosis in SLE patients.

Methods: this is a cross-sectional study, carried on thirty Egyptian SLE patients who fulfilled the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria. All patients had metabolic syndrome were excluded. Twenty healthy individuals, non smokers, matched for age and sex as controls. All patients were subjected to detailed history taking, a complete clinical examination. Laboratory investigations were done and the scores were estimated. The carotid intima-media thickness (CIMT) was assessed by carotid doppler ultrasonography.

Results: There was no statistically significant difference in serum resistin level between SLE patients and healthy individuals (P=0.804). As regards the correlation with disease parameters Serum resistin show statistically significant correlation correlation with hs-CRP (r=0.27*, HDL (r=0.001), and ANA titre (r=0.013), but no significant correlation with HOMA, SLEDAI, SLEDDI, CIMT and different clinical activities. There was a statistically significant difference in CIMT between SLE patients and the controls (P=0.006).

Conclusion: Although serum resistin is correlated with two of cardiovascular risk factors (HDL, hs-CRP), it doesn’t correlate significantly with CIMT in SLE patients. Resistin is correlated to inflammation more than subclinical atherosclerosis. Moreover, SLE patients have higher CIMT than healthy population so SLE is considered a CVD risk factor.

THE ROLE OF ANGIOPOTHIN-LIKE PROTEIN 4 TYPE IN PROGRESSION OF INFLAMMATORY CHANGES IN RHEUMATOID ARTHRITIS

Vladislav Aleksandrova1,2, Ludmila Shilova1, Irina Alekhina1, Nina Alekseev1,2, Hospital for JIA suspected symptoms, but diagnosed as not JIA. Enzyme-linked immunosensor assay (ELISA) was used for detection and quanti- rational JIA (n=3, 3.4%) and oligoarticular JIA (n=3, 2.2%). The sensitivity and specificity of anti-CCP antibodies in all JIA patients was 4.7% and 99.4%.

Conclusion: Anti-CCP antibodies have high specificity for JIA, but its sensitivity is low. Therefore, it can provide additional help for diagnosis of JIA with its high specificity. In particular, anti-CCP antibodies have the highest sensitivity in RF-positive polyarticular JIA than other subgroups, so it can be a more effective diagnostic tool in the subtype.

DIAGNOSTIC VALUE OF ANTI-CYCQL CITRULLINATED PEPTIDE ANTIBODIES FOR JUVENILE IDIOPATHIC ARTHRITIS IN KOREA

Jong Guun Ahn1, Kwang Nam Kim2. Severance Children’s Hospital, Yonsei University College of Medicine, Department of Pediatrics, Seoul, Korea, Rep. of (South Korea);1Hallym University Sacred Heart Hospital, Department of Pediatrics, Anyang, Korea, Rep. of (South Korea)

Background: Anti-cyclic citrullinated peptide (CCP) antibodies are consid- ered to have specificity for rheumatoid arthritis (RA). However, the diagnostic value of anti-CCP antibody has not been proved in juvenile idiopathic arthritis (JIA).

Objectives: The purpose of this study was to access the prevalence of anti-CCP antibodies in Korean children with JIA, and to investigate the diagnostic accuracy of anti-CCP antibodies according to JIA subgroup.

Methods: JIA patients were recruited from Severance Children’s Hospital, Seoul, Korea from 2004 to 2018. Diagnosis of JIA was made by pediatricians according to the International League of Associations for Rheumatology (ILAR) classification. Control group consisted of healthy children with anti-CCP antibodies test, who had visited the outpatient clinic of the hospital for JIA suspected symptoms, but diagnosed as not JIA. Enzyme-linked immunosensor assay (ELISA) was used for detection and quantifi- cation of anti-CCP antibodies.

Results: Study subjects included 295 JIA patients and 165 controls. Among the JIA children, 14 (8.6%) patients were found to be positive for anti-CCP antibodies. 1 (0.6%) of the control group was positive for anti-CCP antibodies. The positive rates of anti-CCP were highest in rheuma- toid factor (RF)-positive polyarticular JIA (n=8, 66.7%), followed by sys- temic JIA (n=3, 3.4%) and oligoarticular JIA (n=3, 2.2%). The sensitivity and specificity of anti-CCP antibodies in all JIA patients was 4.7% and 99.4%.

THE ROLE OF ANGIOPOTHIN-LIKE PROTEIN 4 TYPE IN PROGRESSION OF INFLAMMATORY CHANGES IN RHEUMATOID ARTHRITIS

Vladislav Aleksandrova1,2, Ludmila Shilova1, Irina Alekhina1, NinaAleksandrova2, Natasha Nikolaeva1, Andrey Aleksandrova1,2, Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation; Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskii, Volgograd, Russian Federation; Stavropol State Medical University, Hospital Therapy, Stavropol, Russian Federation

Background: Angiopoietin-like protein 4 (ANGPTL4) is actively involved in the processes associated with inflammation, angiogenesis and lipid metab- olism in rheumatoid arthritis (RA).

Objectives: To study the effect of ANGPTL4 on the features of the inflammatory process in RA.

Methods: The study included 36 RA patients (aged from 33 to 64 years old). A control group (12 people) comprised healthy individuals aged 28 to 52 years old, 28 patients with osteoarthritis (OA) aged 48 to 70 years and 14 people with ankylosing spondylitis (AS) aged 39 to 62 years. Levels of ANGPTL4 in serum were determined by the enzyme immuno- assay using the commercial test systems «Human Angiopoietin-like Pro- tein 4 ELISA» from «Bio Vendor» (Czech Republic). Serum C-reactive protein (CRP) levels, erythrocyte sedimentation rates (ESR), rheumatoid factor (RF) titer, and anti-cyclic citrullinated peptide antibody (anti-CCP) were also measured in patients with RA.

Results: The following results were obtained: the level of ANGPTL4 was significantly higher in patients with RA than in patients with OA, AS, and healthy individuals (p = 0.04, p = 0.021, p = 0.038, respectively). A strong positive correlation was found between the level of ANGPTL4 and the activity of RA according to DAS28 (r = 0.71, p = 0.002). There is no reliable association between ANGPTL4 and anti-CCP (p> 0.05). The ANGPTL4 level in the serum was correlated with levels of ESR (r = 0.42, p = 0.019), CRP (r = 0.49, p = 0.007) and the Sharp score of radiologic change (r = 0.39, p = 0.045) in RA. Hypervascularization rates were significantly correlated with ANGPTL4 in patients with RA (r = 0.38, p = 0.002) according to Doppler data. ANGPTL4 can activate proliferation processes in the synovial membrane by binding to integrin-{gamma}3. Besides,
the concentration of mast cells is increased in the synovium of affected joints. Mast cells significantly influence angiogenesis through the production of proangiogenic cytokines, including ANGPTL4.

Conclusion: Changes of the level of ANGPTL4 in the serum of patients with RA may be a potential biomarker of disease activity, severity of neovascularization, inflammation and development of bone erosion.

THE PRESENCE OF SYNOVITIS IS THE MAIN FACTOR INFLUENCING THE DEVELOPMENT OF PAIN SYNDROME IN ARTHRITIS OF THE KNEE JOINT

Ninel Aleksandrova1, Natalia Nikitina1, Vladimir Aleksandro2, Ludmila Shilova1, Andrey Aleksandro1,2.1 Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russian Federation; 2 Volgograd State Medical University, Hospital Therapy, Volgograd, Russian Federation

Background: Dysfunctions and pain syndrome in lesions of the knee joint can significantly discomfort a sick person and lead to a persistent decrease in physical activity and disability. Often pain syndrome precedes radiographic appearance of the structural changes in the joint and is accompanied by an increase in number of different changes in the synovium according to ultrasound investigation.

Objectives: To investigate the clinical significance of ultrasound criteria of changes in the synovial membrane of the knee joint cavity and its role in the assessment of pain in gonarthritis.

Methods: 30 people aged 30 to 50 years with osteoarthritis of the knee joint were under observation; assessment of the severity of pain in the knee when walking was at least 40 mm on a visual analogue scale (VAS). Ultrasound examination of the knee joint was carried out according to standard procedure using a linear sensor with a frequency of 0.5-12 MHz in an ultrasonic diagnosis system Accuvix V10 (Samsung Medison, Korea).

Results: The evaluation of ultrasound changes was performed in the upper inversion of the knee joint according to the following criteria: the severity of intraarticular effusion (1), synovial proliferation (2), local vascu- larization of the synovial membrane by power doppler (3). All patients were divided into three groups, according to the severity of pain in the knee joint: group I (12 people) - 41-59 mm, group II (10 people) - 60-79 mm, group III (8 people) - 80-100 mm on the VAS scale. By comparing changes in the knee joint by ultrasound data in patients of different groups, the following results were obtained: group I: severity of intraarticular effusion - 10 people (minimal changes in 60%, moderate in 20%, expressed in 20%), synovial proliferation - 4 people (moderate changes in 50%, expressed in 50%), local vascularization of synovium - 6 people (minimal changes in 66.7%, moderate in 16.7%, expressed in 16.6%). Group II: severity of intraarticular effusion - 9 people (55.6%, 22.2% and 22.2%), synovial proliferation - 3 people (0%, 33.3% and 66.7%), local vascularization of the synovial membrane - 4 people (25%, 25% and 50%, respectively); group III: severity of intraarticular effusion - 8 people (62.5%, 12.5% and 25%), synovial proliferation - 5 people (20%, 40% and 40%), local vascularization of the synovial membrane - 3 people (per 33.3%, respectively).

Conclusion: The use of ultrasound in the diagnosis of diseases of the knee joints allows to reliably determine the structural and functional changes in all components of the knee joint. The severity of pain in gonarthritis is most associated with the presence of synovitis in the joint.

DIAGNOSTIC ROLE OF NEUROMUSCULAR ULTRASOUND IN CUBITAL TUNNEL SYNDROME

Fatma As1, Mona Nasr1, Ahmed Hafez2, Adham Khalil2. 1 Minia university, Reumatology and Rehabilitation, Minia, Egypt; 2 Minia university, Reumatology and Rehabilitation, Minia, Egypt; 3 New Kasr El Eini Teaching Hospital, Cairo University, Cairo, Egypt

Background: Cubital tunnel syndrome (CuTS) is the second most common compressive neuropathy of the upper limb following carpal tunnel syndrome and is the most common site for entrapment for the ulnar nerve

Objectives: Our aim is to evaluate the role of ultrasonography (US) as a diagnostic tool for Cubital tunnel syndrome (CuTS) in comparison with nerve conduction study (NCS).

Methods: twenty elbows with CuTS and twenty asymptomatic controls were assessed by NCS and underwent ultrasonography of elbows. Data from patients and controls were compared to determine the diagnostic relations in patients with CuTS and the grade of severity

Results: There was a high degree of correlation between NCS of the ulnar nerve, clinical parameters and variable US measurements. The CSA of the ulnar nerve was the most sensitive parameter and a cut-off point of 9.5 mm² behind medial epicondyle was found to be 100% sensitive and 80% specific. The ulnar nerve ratios (UNR) had a diagnostic accuracy of 95% with 85% specificity.

Conclusion: Ultrasonographic measurements of the ulnar nerve CSA and UNR have a comparable diagnostic value as a non-invasive and an alternative modality for the evaluation of CuTS

EFFICACY AND SAFETY OF ULTRASOUND GUIDED ASPIRATION AND INTRA-LESIONAL CORTICOSTEROIDS INJECTION OF RUPTURED BAKER'S CYST

Mohammed A. Mortada1, Youmma A. Amr2. 1Faculty of medicine,Zagazig University, Rehematology and Rehabilitation, Zagazig, Egypt; 2Faculty of medicine zagazig university, Rhenumatology and rehabilitation, Zagazig, Egypt

Background: Baker’s cyst is the most common mass in the popliteal fossa and results from fluid distension of the gastrocnemio-semimembranosus bursa. The most common complication of Baker’s cyst is the rupture or dissection of fluid into the adjacent proximal gastrocnemius muscle belly, which results in a pseudothrombophlebitis syndrome mimicking symptoms of DVT.

Treatment of ruptured Baker cysts ranged from conservative management to surgical resection. Ultrasonographic guided aspiration and corticosteroids injection may be an effective and easy method of management of these cases. Up to the best of our knowledge, this is the first study to detect the efficacy and safety of ultrasonographic guided aspiration and injections of ruptured Baker cysts.

Objectives: To evaluate the efficacy and safety of ultrasonographic guided aspiration and local corticosteroids of ruptured Baker cysts based on follow-up clinical and sonographic results.

Methods: A retrospective study was conducted on 42 patients (12 males and 30 females, mean age 36 +/- 10 SD years) affected by a ruptured Baker cysts associated to knee joint disorders in the period between January 2013 to January 2019. The diagnosis was done by clinical presentation of acute calf pain, swelling, tenderness at the calf muscles and ultrasonographic evidences of ruptured backer cysts in the form of free fluid collection in the calf connected to a well defined cyst at the back of knee.

All cases were treated by ultrasonographic guided aspiration and intra-lesional injection of corticosteroids once or twice one week a part. Follow up were done on a weekly basis until complete resolution of symptoms then 3 months later. Visual analogue scale (VAS) for calf pain and Rauschning-Lindgren and Lysolm Knee Scoring Scales were used to assess pre/post-injection knee functions.

Results: The primary diagnoses to patients presented with ruptured Baker cyst in this study were as follow: 18 (42.8%) cases with rheumatoid
