Results: Prevalence of IPAF was 10.1%. Of 68 patients with IPAF, 60% were women and mean age at diagnosis was 64.2 ± 13.8 years old. Mean observation period was 27.1 ± 29.6 months. Smoking history was 42.6% (n=29). Treatment including oral glucocorticoid or/and immunosuppressant use were 44.1% (n=30). Exacerbation rate was 25% (n=12). Overall death rate was 5.9% (n=4) and respiratory death rate was 2.9% (n=2).

Comparison of characteristics at diagnosis between the exacerbation group and non-exacerbation group showed that the exacerbation group had a significantly elevated rate of smoking history, KL-6, and SP-D (P = 0.01, 0.006, and 0.03, respectively). We then analyzed transition of KL-6 in patients with IPAF, IIP, or CTD-ILD. KL-6 at baseline in patients with IPAF (1212 ± 1626 U/mL) was higher than those with IIP and significantly higher than those with CTD-ILD (1030 ± 1027 U/mL(P=0.69) and 829.5 ± 1002 U/mL(P=0.024)).

Incidence rate was presented as the number of events per 10,000 person-year with 95% CI. AS, ankylosing spondylitis; IR, incidence ratio; SIR, standardized incidence ratio; CI, confidence interval

MALIGNANCY RISK IN MALE PATIENTS WITH ANKYLOSING SPONDYLITIS

Bora Nam1, Hyoungyoung Kim1, Eun Jin Jung2, Soo-Kyung Cho1, Yoon-Kyung Sung1, Tae-Hwan Kim1.1Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea); 2Andong National University, Department of Information Statistics, Andong, Korea, Rep. of (South Korea)

Background: In recent studies, the association between autoimmune disease and malignancy has been reported. However in Ankylosing spondylitis (AS), a chronic inflammatory rheumatic disease with marked male predominance, the evidence of this relationship is scarce and inconsistent.

Objectives: To determine the overall cancer and site-specific cancer risk in male patients with AS.

Methods: Using the claims database of Health Insurance and Review Assessment (HIRA), male patients with AS without prior cancer history between 2012 and 2014 were enrolled (n=21,780). For the control group, male general population, stratified random samples of claims data were used (n=342,361). All individual was observed up to the development of any cancer, or end of the study period (December 31, 2015). Incidence rates (IR) of overall and site-specific cancer were presented as the number of event per 10,000 person-years. To make fairer comparison between AS patients and general population, we calculated age adjusted incidence ratio by dividing cancer event of general population with corresponding age. The standardized incidence ratio (SIR) was used to represent the association between AS and cancer, accounting for person-years at risk.

Results: During 71,046 person-year, total 552 cases of cancer occurred in male AS group. Prostate cancer was the leading type of cancer in male AS patients (101 cases, IR 14.22, 95% CI 11.44-16.99). And it was followed by liver cancer (70 cases, IR 9.9, 95% CI 7.5-12.2), lung cancer (48 cases, IR 6.8, 95% CI 4.9-8.7), colorectal cancer (45 cases, IR 6.3, 95% CI 4.5-8.2) and stomach cancer (34 cases, IR 6.1, 95% CI 4.2-7.9). Compared to general population, the overall incidence of cancer was increased in patients with AS (SIR 1.25, 95% CI 1.14-1.36).

Conclusion: Male patients with AS have a increased overall cancer risk, especially in pancreas cancer and malignancy of male reproductive system.

ADHERENCE TO THE MEDITERRANEAN DIET AND RISK OF RHEUMATOID ARTHRITIS IN THE FRENCH PROSPECTIVE E3N COHORT STUDY

Vann Nguyen1,2, Carine Salolit3, Amandine Gelot2, Juliette Gambaretti1, Xavier Masuret4, Marie-Christine Bouton-Ruault1, Rachélle Seror4,5, Center for Research in Epidemiology and Population Health – INSERM U1018 – Université Paris Saclay – Université Paris Sud, Villejuif, France; 4AP-Hôpital Bicêtre, Rheumatology, Le Kremlin-Bicêtre, France; 5Centre Hospitalier Régional d’Orléans, Rheumatology, Orleans, France; Université Paris-Sud, Center for Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM UMR 1184, Université Paris-Saclay, Le Kremlin-Bicêtre, France

Background: The Mediterranean diet (MD), widespread in Southern European countries, mainly consists of olive oil, cereal products, fresh or dried fruit and vegetables, nuts, a moderate amount of dairy and meat, and many condiments and spices. It has been associated with significant reduction of overall mortality, cardiovascular diseases, and neoplastic diseases. It has been suggested to have a beneficial effect on rheumatoid arthritis (RA) activity due to its richness in antioxidants and unsaturated fatty acids. However, data on MD as a prevention of RA are limited.

Objectives: To assess the association between adherence to MD and risk of RA in a general population cohort.

Methods: The E3N cohort study (Etude Épidemiologique auprès des femmes de la Mutuelle générale de l’Education Nationale) is a French prospective cohort of 98,995 healthy women included in 1990-91 and followed since then (median follow-up of 28 years). Among women who completed a food-frequency questionnaire, we calculated the modified MD score (from 0 to 9) according to the consumption status of nine food components. Incident RA cases were detected using a validation process using a specific validation questionnaire and a drug reimbursement database. Hazard ratios (HRs) and 95% confidence intervals (CIs) for incident RA were estimated using Cox proportional hazards regression models with age as the time scale, and adjusting for known risk factors of RA and potential confounders. Because of the known importance of smoking on RA risk, we performed analyses adjusted and stratified on the smoking status.

Results: Among 62,630 women, 480 incident RA cases were diagnosed after a mean (± standard deviation) of 11.7 (± 5.9) years after the food-frequency questionnaire. In the whole cohort, high adherence to MD was not associated with a decreased risk of RA (HR for a 6-9 vs. 0-3 score = 0.86, 95% CI: 0.68–1.09, Plinear trend = 0.11). However, among ever-smoking women (current or past smokers), high adherence to MD was associated with a decreased risk of RA (HR for a 6-9 vs. 0-3 score = 0.77, 95% CI: 0.53–1.05, Plinear trend = 0.025), while there was no association in non-smokers (HR for a 6-9 vs. 0-3 score = 0.98, 95% CI: 0.70–1.38, Plinear trend = 0.90).

HR (95% CI) for RA according to the MD score

* HRs were adjusted for age, educational level, body mass index, smoking status, passive smoking during childhood, energy intake, physical activity, gastrointestinal transit.

Conclusion: High adherence to a MD could reduce RA risk in ever-smoking women. Further studies are needed to confirm our findings.

ANTIPePTIDYL-ARGININE DEIMINASE 3 AND 4 AUTOANTIBODIES IN A COHORT OF RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE

Boaz Palterer1, Gianfranco Vitiello2, Bernardo D’Onofrio2, Emanuele Vivarelli2, Daniele Cammelli2, Maria Grazia Giudizi2, Laura Martinez-Prat2, Silvia Casas2, Chelsea Bentow3, Michael Mahler4, Paola Parronchi4, University of Florence, Department of Clinical and Experimental Medicine, Firenze, Italy; 2Inova Diagnostics, Inc., San Diego, United States of America

Background: Interstitial lung disease (ILD) affects up to 30% of patients with rheumatoid arthritis (RA). Peptidylarginine deiminases (PAD) are key enzymes in RA pathogenesis as they are involved in the citrullination of proteins, targets of anti-citrullinated protein antibodies (ACPA). Although RA-ILD significantly contributes to disease burden including mortality, diagnostic and prognostic biomarkers are still lacking.

Objectives: To measure anti-PAD3 and anti-PAD4 antibodies in a cohort of RA and compare their prevalence in patients with and without ILD. To assess the associations of anti-PAD3, anti-PAD4 and ACPA with disease activity, joint erosions, lung involvement and smoking history.

Methods: A total of 71 patients fulfilling the 2010 ACR/EULAR RA Classification Criteria were recruited; the mean age was 63±12.4 and 87% of them were females, 11 (15.5%) of them had been diagnosed with ILD. Demographic, clinical as well as radiological data were retrospectively collected. ILD was defined as usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP) or indeterminate patterns on chest high-resolution computed tomography, according to ATS/ERS guidelines. Particle-based Multi-Analyte Technology (PMAT) (Inova Diagnostics, USA, research use only) was used to measure anti-PAD3 and anti-PAD4 autoantibodies. ACPA IgG were measured by chemiluminescence (QUANTA Flash CCP3, Inova Diagnostics, USA).

Results: Anti-PAD4 levels were correlated with erosive disease (p=0.043) and morning stiffness (p=0.031). Anti-PAD3 and anti-PAD4 levels were associated with DAS28-ESR at the time of sampling (anti-PAD3, r=0.34, p=0.004; anti-PAD4, r=0.34, p=0.004). Anti-PAD4 antibodies were significantly lower in patients with ILD (p=0.043). There was no association between anti-PAD4 and smoking, while anti-PAD3 antibodies were higher in non-smokers (p=0.004). A strong correlation was found between anti-PAD4 and anti-PAD3 levels (r=0.73, p<0.0005).

Conclusion: In our cohort, anti-PAD4 antibodies were correlated with joint erosions and RA disease activity, whereas a negative association with ILD was found. Smoking history was not associated with the presence and levels of anti-PAD antibodies. Our data validate the usefulness of anti-PAD4 antibodies as a biomarker for erosive disease. Further studies that take into account relevant confounders like therapy and larger RA-ILD cohorts are needed.
