SAT0305  PERFORMANCE OF HIGH FREQUENCY ULTRASOUND IN THE ASSESSMENT OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS

G. Lettieri1, V. Picerno2, D. Temiz Karadag3, M. C. Padula2, G. A. Meninilli2, A. Padula2, S. D’angelo2, G. Abignano1. 1Radiology Department, San Carlo Hospital, Potenza, Italy; 2Rheumatology Institute of Lucania (IReL), Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy; 3Canakkale State Hospital, Rheumatology Clinic, Canakkale, Turkey

Background: The modified Rodnan skin score (mRSS) is the current gold standard for skin assessment in systemic sclerosis (SSc) both in clinical trials and practice. High frequency ultrasound (HFUS) has been suggested to offer a quantitative assessment of skin thickness in SSc by several studies, however results are inhomogeneous with regards to the machine used, number of imaged sites, as well as the various stages of skin involvement.

Objectives: Aim of this cross-sectional study was to compare performance of HFUS in the assessment of skin involvement in diffuse cutaneous SSc (dcSSc) patients, at different disease stages, as compared with healthy controls (HC).

Methods: Dorsal finger, hand, forearm and upper arm skin of consecutive dcSSc patients, at different disease stages, and of matched-HC were scanned bilaterally using HFUS. Two investigators, expert in MSK ultrasound, blinded to the clinical details, measured skin thickness using Esaote MyLab70 equipped with a 22 MHz probe. Clinical involvement was assessed by a blinded operator using the mRSS and results were compared with imaging data. Statistical analysis was performed using GraphPad Prism software V.7.0.

Results: A total of 704 HFUS images were obtained from 22 dcSSc patients [20 Female, mean age 49 ±11 years, 12 with ≤ 5 years disease duration] and 22 HC [20 Female, mean age 50.7 ±8.7 years]. Skin thickness was significantly higher in SSc patients than in HC at fingers (p<0.0001) and hands (p<0.001), while no significant difference was found at the forearms and upper arms (p>0.05). HFUS showed a good discriminative ability between SSc and HC skin at fingers and hands (AUC 0.91, 0.81, 0.6 and 0.65 for fingers, hands, forearms and upper arms respectively). When analysing the subgroup of SSc patients with ≤5 years disease duration, HFUS showed a slightly lower performance in discriminating between SSc without clinical skin involvement (site mRSS=0) and HC (AUC 0.68, 0.57, 0.68 for hands, forearms and upper arms respectively). Mean HFUS skin thickness significantly correlated with mRSS at site of analysis (hand: r=0.78, p<0.0001; forearm: r=0.47, p=0.0013; upper arm: r=0.52, p=0.0003) and total mRSS (hand: r=0.53, p=0.0002; forearm: r=0.63, p<0.0001; upper arm: r=0.63, p<0.0001). No significant correlation was found between finger skin thickness and mRSS (both local and total, p>0.05). Interoobserver reliability for skin thickness was good to excellent at all sites with intraobserver correlation coefficient ranging between 0.79 and 0.94.

Conclusion: HFUS of the skin is a reliable measure of skin involvement in SSc. Studies with higher number of patients with different clinical features are needed to explore the potential of HFUS to discriminate between healthy and SSc skin, including sites at a preclinical stage of involvement.

SAT0307  PROGRESSION OF SUBCLINICAL MYOCARDIAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

D. Benferego1, G. Stronati2, L. Manfredi1, L. Zuliani1, A. Ferrarini1, C. Fischetti1, C. Dichiara1, F. Guerra1, D. Aello Russolo2, A. Gabrielli1, 1Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari, Ancona, Italy; 2Università Politecnica delle Marche, Dipartimento di Scienze Biomediche e Sanità Pubblica, Ancona, Italy

Background: Systemic sclerosis (SSc) is a progressive autoimmune disease affecting the skin as well as internal organs, including the heart. A few studies have identified a subclinical heart involvement in patients with no pulmonary hypertension. Changes in myocardial deformation are consistent with the idea of SSc-related cardiomyopathy as a primary condition affecting the heart globally through microvascular dysfunction and subsequent myofibrillar fibrosis.

Objectives: The aim of the present study is to describe the progression of myocardial deformation in patients with SSc and no overt cardiac disease.

Methods: Prospective longitudinal study enrolling consecutive SSc patients referred to the Clinica Medica, University Hospital “Ospedali Riuniti”, Ancona, Italy, from February 2016 to December 2018. All patients fulfilled the 2013 ACR/EULAR classification criteria for SSc. Patients with structural heart disease, heart failure, atrial fibrillation or pulmonary hypertension were excluded. Disease subset, antibodies pattern, cardiovascular risk factors and involvement of other organ systems were recorded for each patient. An echocardiographic exam was performed for all patients at baseline and during their follow-up evaluation. Standard and speckle-tracking derived variables for the systolic and diastolic function of the left ventricle (LV) and right ventricle (RV) were acquired. Speckle tracking analysis software (EchoPAC 13.0; GE Medical Systems, Milwaukee, USA) was used to assess the GLS of the left and right ventricle, excluding the ventricular septum from right ventricular GLS calculations.

Results: Seventy-two patients (68 females, age 56.6±15.4 years) were enrolled. Common echocardiographic parameters of left and right systolic function were within normal range at baseline and did not change during follow-up. Mean GLS, however, worsened for both left (from -19.8±3.5% to -18.7±3.5%, p=0.034) and right ventricle (from -20.9±6.1% to -18.7±5.4%, p=0.013) during a median follow-up of 20 months (1st-3rd quartile 12-24 months). The increased impairment registered in SSc patients was homogenous across endocardial layers (LV from -22.5±3.9 to -21.4±3.9, p=0.001; RV from -24.2±6.2 to -20.8±5.9, p=0.001), mesocardial layers (LV -19.7±3.6 to -18.7±3.5, p=0.043; RV from -21.3±5.9 to -18.8±5.7, p=0.012) and epicardial layers (LV from -17.1±3.0 to -16.4±3.1, p=0.12; RV -18.8±6.3 to -16.0±8.4, p=0.035), as well as

SAT0305  SEMIQUANTITATIVE AND QUANTITATIVE ANALYSIS OF LUNG CT IN THE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOPATHIES WITH A FOCUS ON ANTISYNTHETASE

S. Banzato1, C. Roncella2, A. Valentini3, L. Cavagna4, R. Castellana4, E. Cioffi1, A. Tripoli1, D. Caramella5, B. Bartholmai6, R. Neri1, F. Falaschi2, C. Romei2. 1Rheumatology Unit - Pisa University Hospital, Pisa, Italy; 2Department of Radiology, University and IRCCS Policlinico S. Matteo Foundation, Pavia, Italy; 3Department of Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy; 4Department of Rheumatology, Mayo Clinic, Rochester, United States of America

Background: Intestinal lung disease (ILD), is common in patients with idiopathic inflammatory myopathies (IIM) and strongly impact on patients’ morbidity and mortality. Patients with anti-aminocetyl-transfer RNA-synthetases (anti-ARS) antibodies are associated with an increased risk of ILD.

Objectives: Defining the radiological characteristics of IIM patients, with special focus on serological groups, through qualitative, semi quantitative and quantitative analysis of lung CT.

Methods: This was a prospective study conducted from 2016 to 2019. Ninety-eight IIM patients (35 men, 63 women) were included. Myositis autoantibodies (MSA) were assessed with Myositis Prophylle III (Euroimmune, Lubeck).

Each patient had a baseline CT; the total score of Warwick (WS) was obtained at semiquantitative analysis. The radiological scores ILD% (interstitial lung disease %) and PVRS% (pulmonary vascular related structure) were the result of quantitative analysis in 61 patients (CALIPER). Pulmonary function tests (PFTs) included TLC%, FVC% and DLCO% (65 patients). The analysis was conducted in the whole group and divided in subgroups based on their MSA pattern: in particular anti-ARS (Group 1) and patients negative to MSA (Group 2) were analysed.

Results: Positive correlations between ILD% and PVRS% (ILD% Rho=0.916, p=0.000, WS and ILD% (ILD% Rho=0.663, p=0.000) and WS and PVRS% (Rho=0.637, p<0.001) were found.

The most relevant inverse correlations were found between ILD% and DLCO% (Rho=-0.592, p=0.001), PVRS% and DLCO% (Rho=-0.549, p<0.001) and WS and DLCO% (Rho=-0.471, p=0.001).

Statistically significant higher values of WS, ILD% and PVRS% were found in Group 1 (WS=15, ILD%11 and PVRS%=3.5), compared to Group 2 (WS=2.5, ILD%=0.84 and PVRS%=2.2). NSP pattern resulted dominant represented in the two groups (80% Group 1, 75% Group 2). No statistically significant differences of DLCO%, FVC% and TLCO% were found.

Conclusion: The inverse correlations between the radiological scores and the functional data TLC%, FVC% and DLCO% were found.
