Background: Objectives: Assess the severity of coronary atherosclerosis in men with coronary heart disease (CHD) depending on bone mineral density (BMD).

Methods: Two-hundred and two men who verified CHD aged 51-75 (50.8 ± 6.9) were examined. All patients performed two-energy X-ray absorption of lumbar vertebral bodies LI-LIV and hip necks (Excell XR-46, Norland, USA) and polyprojector coronangiography (Innova, General Electric, USA). On the basis of results of densitometry on value of T-criterion (the recommendation of ISCD, 2007) estimated BMD condition: normal BMD (T criterion ≥1), osteopenia (T-criterion from -1 to -2.5) and osteoporosis (T criterion < -2.5). According to the SYNTAX scale (www.syntaxscore.com), the following degrees of coronary artery (CA) injury severity were isolated to quantify the expression of atherosclerotic injury: low (22 or less), intermediate (23-32) and high (33 or more). According to the result of multipolar computed tomography of CA, calcium index of vessels was determined by the Agastoun method using the CaScore program. On the basis of the calcium index value, the degree of calcinosis was evaluated: 0 - absence of calcinosis, 1-10 minimal, 11-100 - moderate, 101-400 - increased, more than 400 - expressed calcinosis.

Results: According to the results of densitometry, patients were found to have 21 patients (20.6%) with normal BMD, 48 (47.0%) - osteopenia and 32 (32.4%) - osteoporosis. Osteoporotic syndrome (OPS) was found in 79.4% of men. All patients tested, depending on the degree of CA calcinosis, were distributed as follows: 57.8% of men had pronounced CA calcinosis, 25.5% - increased, 6.9% - moderate, 2.0% - minimal, 7.8% of patients had no CA calcinosis. In a comparative analysis of the degree of coronary calcinosis in men with CHD depending on the T-criterion, it was found that the majority of patients with OPS (69.7% of patients with OP and 60.4% with OPe) had pronounced CA calcinosis. In men with normal BMD, the prevalence of pronounced CA calcinosis (33.3%) was significantly lower than in patients with OPS (p = 0.050). Calcinosis-negative CA was recorded reliably more frequently in patients with normal BMD (28.6%) compared to men with low BMD (p < 0.050). The results of the work demonstrated the relationship of the studied parameters of coronary atherosclerosis expression with densitometry indicators in men with CHD. Thus, the inverse correlation of the BMD at the level of the hip neck with the number of significant stenoses of the space (r = -0.19; P = 0.045) and the degree of coronary calcinosis (r = 0.37; P = 0.023) and similar dependence of BMD of the L3 level with coronary calcinosis degree (r = 0.23; P = 0.19; r = 0.046). A direct correlation between CA calcinosis and FRAX hip fracture risk (r = 0.24; p = 0.018). Inverse correlation of parameters of atherosclerotic damage of CA (number of significant stenoses and degree of calcinosis) with BMD was established, and direct correlation of CA calcinosis degree with risk of hip fracture on FRAX scale in male persons with CHD over 50 years of age was revealed.

Conclusion: The findings suggest in favor of likely common mechanisms for developing atherosclerosis with OP and allow coronary calcinosis to be considered as a condition potentially increasing the risk of hip fracture.

SAT0481 RELATIONSHIP BETWEEN SARCOPENIA AND BONE MINERAL DENSITY IN MEN WITH CORONARY HEART DISEASE

I. Grigoreva1, T. Raskina1, J. Averkieva1, M. Letaeva1, O. Malyshenko1, K. Krivoshapova1, V. Fanaskov1, 1Federal State Educational Institution of Higher Education “Kemerovo State Medical University”; Kemerovo, Russian Federation; 2Research Institute for Complex Problems of Cardiovascular Diseases, Siberian Branch, Russian Academy of Medical Sciences, Kemerovo, Russian Federation; 3State Autonomous Healthcare Institution of the Kemerovo Region “Regional Clinical Hospital for War Veterans”; Kemerovo, Russian Federation

Objectives: To study the relationship of indicators of muscle mass, muscle strength and muscle function with bone mineral density (BMD) in men with coronary heart disease (CHD).

Methods: 79 men aged over 50 years with verified CHD were examined (mean age 63 (57; 66) years.

The BMD (g/cm²) and T-criterion (standard deviation) of the femoral neck and lumbar spine (L1-L4) were evaluated using dual-energy X-ray absorbtiometry (DXA) on the lunar Prodigy Prime bone densitometer (USA). To assess muscle strength, the total area (cm²) of the lumbar muscles of the axial section at the level of the 3rd lumbar vertebra (L3) was determined using mul-tispiral computed tomography on a 64-slice computer tomograph “Somatom Sensation 64” (Siemens AG Medical Solution, Germany). The ratio of the obtained index of the area of skeletal muscle to the square of the patient’s growth index (skeletal index) was found (r= -0.260, p=0.021). The relationship between muscle strength and muscle function with bone mineral density (BMD) in men with coronary heart disease (CHD) depending on bone mineral density (BMD).

Results: To assess muscle strength, the total area (cm²) of the lumbar muscles of the axial section at the level of the 3rd lumbar vertebra (L3) was determined using multispiral computed tomography on a 64-slice computer tomograph “Somatom Sensation 64” (Siemens AG Medical Solution, Germany). The ratio of the obtained index of the area of skeletal muscle to the square of the patient’s growth index (skeletal index) was found (r= -0.260, p=0.021). The relationship between muscle strength and muscle function with bone mineral density (BMD) in men with coronary heart disease (CHD) depending on bone mineral density (BMD). A decrease in muscle strength correlates with the severity of bone loss, while a decrease in muscle function correlates with a decrease in muscle mass. The results obtained confirm the probability of common mechanisms in the development of sarcopenia and osteoporosis in men with CHD.

SAT0482 FRAX 10-YR FRACTURE RISK IN RHEUMATOID ARTHRITIS ASSESSED WITH AND WITHOUT BONE MINERAL DENSITY – ARE WE TREATING OUR PATIENTS UNDER BDMARDS?

M. Fato1, F. Pinheiro1, S. Garcia1, B. M. Fernandes1, S. Ganhão1, R. Gaio1, M. Bernardes1, A. Bernard1, L. Costa1, Centro Hospitalar Universitário de São João, Rheumatology, Porto, Portugal; 2Faculdade de Ciências da Universidade do Porto & Centro de Matemática da Universidade do Porto, Mathematics, Porto, Portugal

Background: Patients with rheumatoid arthritis (RA) have a higher risk of osteoporosis not only due to chronic inflammation status, but also due to the treatment with glucocorticoids. FRAX is a computer-based algorithm developed by the World Health Organization for estimation of the 10-year risk of a hip or major osteoporotic fracture. Inclusion of femoral neck bone mineral density (BMD) in the estimation is optional.

Objectives: The study aimed to identify the RA patients under treatment with biological disease-modifying antirheumatic drug (bDMARD), who have FRAX scores, calculated with and without BMD, classified as high fracture risk and evaluate if they are receiving treatment for osteoporosis. The authors also investigated the intra-individual agreement between FRAX fracture risk calculated with and without BMD.

Methods: Demographic and clinical data and BMD results from RA patients followed in a tertiary university hospital and registered in the Rheumatic Diseases Portuguese Register were used for analysis. Patients under 40 years of age at the last visit were excluded. McNemar test was applied for the identification of discordance of risk categories. The Wilcoxon test was used to characterize the intradividual differences between paired FRAX risks with and without BMD. Correlations between pairs of variables were evaluated by the Spearman test. For independent variables Mann-Whitney test was used.

Results: A total of 303 patients were included, 244 were females (80.5%) and 49 current smokers (16.2%). Mean age was 59.5 ± 9.54 years and mean disease duration 18.5 ± 10.4 years. Two hundred and twenty patients (72.4%) and 243 (80.2%) were RF and ACPO positive, respectively, and 51.5% had erosive disease. Mean disease activity score (DAS28-4V-CRP) was 3.08 ± 1.18 and mean femoral neck BMD 0.84 ± 0.12 g/cm². One hundred and seventy-nine patients (58.9%) were concomitantly treated with conventional synthetic DMARDs and 215 (70.7%) with glucocorticoids. Among all the patients, 35 (11.8%) had previous fractures and 19 (6.3%) have family history of fracture. The median 10-year risk of a major fracture and a hip fracture, calculated without BMD, was 6.0 (12.5-83.9) and 1.7 (0-61) and 1.7 (0-49). When FRAX score is calculated without BMD (n=303), 76 (25.1%) patients were categorized as high fracture risk. Among them, only 41 (54%) were receiving osteoporosis treatment. FRAX assessment with BMD (n=231) identified 99 (32.7%) patients with high fracture risk, 51 (51.5%) in each treatment group. The median 10-year risk of a major fracture and a hip fracture, calculated without BMD, was 6.9 (1.3-61) and 1.7 (0-49). When FRAX score is calculated without BMD (n=303), 76 (25.1%) patients were categorized as high fracture risk. Among them, only 41 (54%) were receiving osteoporosis treatment. FRAX assessment with BMD (n=231) identified 99 (32.7%) patients with high fracture risk, 51 (51.5%) in each treatment group.
