Background: The investigation of anti-inflammatory and immunosuppressive functions of kynurenic acid (KYNA) is now in focus. Previously, we demonstrated the opposite effects of KYNA and different KYNA analogs on tumor necrosis factor- α (TNF- α) production and tumor necrosis factor-stimulated gene-6 (TSG-6) expression in U-937 monocytic cells. The potential effect of KYNA analogs on further immune mediators including alarmins (S100A12=EN-RAGE and S100A8/9=calprotectin), and on human neutrophil peptide 1-3(α -defensin) production has not been investigated.

Objectives: Therefore, in the present study, we compared the effects of newly synthesized KYNA analog on the TNF- α , alarmins and α -defensin production, correlation with the effects on the TSG-6 expression in rheumatoid arthritis (RA).

Methods: 93 RA patients were involved and divided subgroups based on DAS28 activity score. Peripheral blood mononuclear cells (PBMC) was isolated from RA patients and healthy controls. As cytokine inducers heat inactivated *Staphylococcus aureus* (SA1) were used. In parallel in vitro experiments, the SA1 induced PBMCs were pretreated with a newly synthesized KYNA analog (compound SZR-72 was synthesized by direct amidation of KYNA). The concentrations of the above mentioned inflammatory mediators in the supernatants were quantified by using ELISA kits and the TSG-6 expression was also determined by RTqPCR method.

Results: The SA1 induced TNF- α , EN-RAGE, calprotectin and α -defensin production was significantly higher in RA patients' group than in healthy controls. KYNA analog attenuated the SA1 induced TNF- α , EN-RAGE, calprotectin and α -defensin production, and increased TSG-6 production and TSG-6 mRNA expression in PBMC cells from RA patients. The SA1 induced TNF- α and TSG-6 production correlated with the DAS28 activity score. The TNF- α inhibitory effect of the KYNA analog correlated inversely with the TSG-6 stimulatory effect in all subgroups of RA patients based on DAS28 activity score.

Conclusion: TSG-6 expression could participate in the suppression of inflammatory cytokines, such as TNF- α , EN-RAGE, calprotectin and α -defensin. We suppose that the elevation of the TSG-6 expression by KYNA and especially by new KYNA analogs might be one of the mechanisms that are responsible for their suppressive effect on TNF- α production as a feedback mechanism in RA. KYNA and KYNA analogs have an important role in influencing TSG-6 expression, and there is a possible benefit with potential therapeutic consequence of targeting TSG-6 expression by kynurenines in inflammatory conditions in RA.

IRAK4 INHIBITION SUPPRESSES PROINFLAMMATORY CYTOKINE PRODUCTION FROM HUMAN MACROPHAGES STIMULATED WITH SYNOVIAL FLUID FROM RHEUMATOID ARTHRITIS PATIENTS

A. Yadon¹, D. Ruelas², G. Min-Oo², J. Taylor², M. R. Warr². ¹Gilead Sciences, Inc., Seattle, United States of America; ²Gilead Sciences, Inc., Foster City, United States of America

Background: Rheumatoid arthritis (RA) is characterized by chronic, uncontrolled joint inflammation and tissue destruction. Macrophages are thought to be key mediators in both the initiation and perpetuation of this pathology.^{1,2} The RA synovium contains a complex inflammatory milieu that can stimulate macrophage-dependent production of proinflammatory cytokines through multiple signaling pathways.^{1,2} Existing evidence indicates that toll-like receptors (TLRs) and interleukin-1 receptors (IL-1R) along with their agonists, damage-associated molecular patterns (DAMPs) and IL-1 β , are highly expressed in RA joints and are important mediators of synovial macrophage activation and proinflammatory cytokine production.¹⁻⁹ IRAK4 (interleukin-1 receptor-associated kinase 4) is a serine/threonine kinase that facilitates TLR and IL-1R signaling in many cell types, including macrophages.¹⁰ IRAK4 inhibition represents an opportunity to reduce proinflammatory cytokine production in the joints of patients with RA.

Objectives: To investigate the effect of a highly selective IRAK4 inhibitor on proinflammatory cytokine production from human macrophages stimulated with synovial fluid from patients with RA.

Methods: Primary human monocytes from 2 independent donors were differentiated for 6 days with granulocyte-macrophage colony-stimulating factor (GM-CSF) to generate human monocyte-derived macrophages (hMDMs).

hMDMs were then pretreated with an IRAK4 inhibitor for 1 hour and subsequently stimulated for 24 hours with RA synovial fluid from 5 patients. Culture supernatants were then assessed for secretion of proinflammatory cytokines by MesoScale Discovery.

Results: RA synovial fluid stimulation of hMDMs resulted in the production of several proinflammatory cytokines, including IL-6, IL-8, and TNF α . Pretreatment of hMDMs with an IRAK4 inhibitor resulted in the dose-dependent inhibition of IL-6, IL-8, and TNF α production, with an average EC₅₀ $\pm$ SD of 27 $\pm$ 31, 26 $\pm$ 41, and 28 $\pm$ 22 nM, respectively. Maximal percent suppression $\pm$ SD of IL-6, IL-8, and TNF α were 76 $\pm$ 8.8, 73 $\pm$ 15, and 77 $\pm$ 13, respectively. To evaluate the specific IRAK4-dependent signaling pathways mediating this response, hMDMs were pretreated with inhibitors of TLR4 (TAK242) and IL-1R (IL-1RA) prior to stimulation with RA synovial fluid. Both TAK242 and IL-1RA inhibited proinflammatory cytokine production. For TAK242, maximal percent suppression $\pm$ SD of IL-6, IL-8, and TNF α were 39 $\pm$ 25, 48 $\pm$ 24, and 50 $\pm$ 21, respectively. For IL-1RA maximal percent suppression $\pm$ SD of IL-6, IL-8, and TNF α were 18 $\pm$ 18, 20 $\pm$ 23, and 16 $\pm$ 18, respectively. The broad range of inhibition across each stimulation highlights the complexity and variability in the signaling pathways mediating proinflammatory cytokine production from hMDMs stimulated with RA synovial fluid, but demonstrates that RA synovial fluid can stimulate proinflammatory cytokine production in hMDMs, at least partly, through IRAK4-dependent pathways.

Conclusion: This work demonstrates that IRAK4 inhibition can suppress proinflammatory cytokine production from macrophages stimulated with synovial fluid from patients with RA and supports a potential pathophysiological role for IRAK4 in perpetuating chronic inflammation in RA.

THE ROLE OF CD70 IN THE DEVELOPMENT OF RHEUMATOID ARTHRITIS

S.-J. Yoo¹, S. W. Kang¹, J. Kim¹, I. S. Yoo¹, C. K. Park¹, H. R. Lee¹. ¹Chungnam National University Hospital, Daejeon, Korea, Rep. of (South Korea)

Background: Rheumatoid arthritis (RA) is a progressive, chronic inflammatory autoimmune disease. Pro-inflammatory molecules, activated lymphocytes, and the migration of inflammatory cells are important in the development of RA. There are many unknown causes of RA. And there are many patients who are refractory to treatment with known disease-modifying anti-rheumatic drugs. So, unknown cause of RA needs to be elucidated.

CD70 is a member of the tumor necrosis factor (TNF) superfamily and a ligand for CD27. The interaction of CD70 with its receptor CD27 promotes expansion and differentiation of memory and effector T cells as well as B-cell expansion and plasma cell differentiation. Hypoxia is an important micro-environmental factor in RA synovium. Hypoxia induces activation of hypoxia inducible factor (HIF). The expression of HIF-2 α is up-regulated in human RA synovium. Reactive oxygen species (ROS) has been implicated in the pathophysiology of RA.

Objectives: In this study, we tried to examine the presence of CD70 in RA synovium and investigate the role of CD70 in the development of RA associated with HIF-2 α and ROS.

Methods: Fibroblast-like synoviocyte (FLS), peripheral blood (PB) and synovial fluid (SF) were used for experiments. FLS was stimulated with recombinant human (rh)-IL-17 and rh-TNF- α . N-acetyl-L-cysteine (NAC) was used as a ROS scavenger. HIF-2 α inhibitor (PT-2385) was used to examine the effect of HIF-2 α in RA-FLS. RT-PCR, qPCR, western blotting, flow-cytometry, ELISA, cell migration assay, and scratch wound assay were performed.

Results: CD70 mRNA is present and elevated by stimulation with IL-17 and TNF- α in both RA-FLS and osteoarthritis (OA)-FLS (Fig 1). CD70 also expresses on the surface of RA-FLS and OA FLS (Fig 2). CD70 expression on the surface of FLS is elevated by stimulation with IL-17 and TNF- α in both
