Background: Enthesitis anatomy and biomechanics have a key role in Spondyloarthritis (SpA) pathogenesis [1] but few data are available about the influence of structural and biomechanical changes of Achilles tendon (AT) on persisting pain in longstanding SpA patients.

Objectives: To correlate AT pain in longstanding SpA patients with ultrasonographic detectable disorders and biomechanical abnormalities.

Methods: We performed a monocentric cross-sectional analysis including 35 consecutive patients affected by SpA (13 with Psoriatic Arthritis, 9 with Enteropathic SpA, 6 with Ankylosing Spondylitis and 7 with Undifferentiated SpA) under treatment with anti-TNF agents. A rheumatologic clinical and clinimetric evaluation (AT pain BASDAI, BASFI, HAQ), an ultrasound study of AT according to the Madrid Sonographic Enthesis Index (MASEI) score and a podiatrist biomechanical evaluation [Foot posture index (FPI), degree of ankle dorsiflexion with the knee extended and flexed] were performed.

Results: Study population (13 F; 22M; mean age 54.9 ±13.9 years; mean disease duration 9.5 ± 5.0 years; mean BMI 25.8 ±4.4) showed a mean AT VAS pain of 3.4 ± 2.2, a mean HAQ of 0.6 ± 0.6, a mean BASDAI of 3.3 ±2.1 and a mean BASFI of 2.2 ±1.9. At the ultrasonographic evaluation 47% (33/70) of the AT entheses analysed presented a dishomogeneous echostructure, 31% (22/70) structural thickness, 53% (37/70) calcifications, 10% (7/70) erosions, 44% (31/70) a retrocalcaneal bursitis. A power Doppler positivity was found only in 0.07% (5/70) of the AT. At the biomechanical evaluation 50% (35/70) of the feet showed a FPI score between 0 and +5 (neutral foot), 46% (32/70) a FPI score between +6 and +9 (slight foot pronation) and 6% (4/70) a FPI score between -1 and -4 (slight foot supination).

The mean degree of ankle dorsiflexion with extended knee was 8.4 ± 3.9 with the 61% (43/70) of the patients with a maximum dorsiflexion < 10° of whom 46% (20/43) do not recover after the knee flexion. We found a between the mean degree of left ankle dorsiflexion with extended/ flexed knee both with ultrasound-revealed left AT enthesis calcifications (p=0.014/0.037) and with left AT enthesis thickness (p=0.049/0.035), and a significant association between the mean degree of right ankle dorsiflexion and extended/flexed knee and ultrasound-revealed right AT calcifications (p=0.008/0.012). Moreover, we noticed an inverse correlation between the overall mean degree of ankle dorsiflexion with extended/flexed knee and the BASFI values (p=0.007/0.004). AT pain was statistically related with Achilles PDUS signal persistence (p=0.048) but not with US signs of chronic enthesopathy or biomechanical alterations [calcification (p=0.39), erosions (p=0.74)]. The limits of the study were the low number of patients recruited and the lack of a control group.

Conclusion: In this monocentric study on a cohort of SpA patients, we demonstrated a statistically significant correlation between ankle–subtalar joint complex biomechanical alterations, ultrasonographic signs of chronic enthesopathy and clinimetric index of functional disability. Residual Achilles pain seems to be related to US signs of active enthesitis.

CLINICAL CHARACTERISTICS OF RADIOGRAPHIC AND NON RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN A GROUP OF TUNISIAN SPONDYLOARTHRITIS

K. Ben Abdelghani1, Y. Gazm1, A. Faza1, S. Miladi1, K. Ouenniche1, S. Kassa1, L. Souabni1, S. Chekili1, A. Laatar1,2, Mongi Slim Hospital, Montagut, Tunisia

Background: In the literature, non radiographic axial Spondyloarthritis (nrSpA) is predominantly female with a shorter period of evolution and similar peripheral manifestations to radiographic axial spondyloarthritis (rSpA). However, we do not have Tunisian studies comparing the two groups of axial spondyloarthritides (axSpA).

Objectives: The aim of this study was to assess the epidemiological and clinical differences between nrSpA and rSpA in a group of Tunisian axSpA.

Methods: Two hundred patients with axSpA (ASAS 2009 criteria) were retrospectively included and classified as rSpA characterized by the presence of radiographic sacroilitis and nrSpA defined by the presence sacroilitis only on MRI or HLA B27 antigen with other clinical features. The different demographic and clinical parameters were compared between the nrSpA and rSpA groups.

Results: One hundred thirty-eight men and 62 women were included with a sex ratio of 2.2. The mean age was 43.3 ± 11.2 years and the mean period of evolution was 10.7 ± 8.4 years. The patients were divided to rSpA in 80% of cases (n = 160) and nrSpA in 20% of cases (n = 40).

Women were more present in the nrSpA group with 47.5% of women versus 26.8% of women in the rSpA group (p = 0.01). The patients with nrSpA were younger with a mean age of 39.4 ± 13.4 years versus 44.3 ± 10.4 years in patients with rSpA (p = 0.03). The mean period of evolution was shorter in nrSpA group (5.8 ± 4.9 years vs 11.9 ± 8.5; p <0.001). The family history of SpA was more frequent in nrSpA group (17.5% vs 4.3%, p = 0.004). Arthritis were more frequent in nrSpA (42.5% vs 13.7%; p <0.0001). Similarly, enthesis were more frequent in nrSpA group (45% vs 15.6%; p <0.0001).

No statistically significant differences were found in the following parameters: age at onset of symptoms, diagnostic delay, HLA B27 antigen and dactylitis.

Conclusion: The clinical features were different in the 2 groups of axSpA: Patients with nrSpA were more female and had more peripheral manifestations while patients with rSpA were older and with longer period of evolution.

PARTICULARITIES OF TUNISIAN FEMALE AXIAL SPONDYLOARTHRITIS

K. Ben Abdelghani1, Y. Gazm1, A. Faza1, S. Miladi1, K. Ouenniche1, S. Kassa1, L. Souabni1, S. Chekili1, A. Laatar1,2, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia

Background: Axial spondyloarthritis (axSpA) is a chronic rheumatic disease that mainly affects men. However, the female form of axSpA remains insufficiently studied.

Objectives: The aim of this study was to determine the clinical characteristics, the disease activity and the functional impact of female axSpA in comparison with male axSpA.

Methods: This is a retrospective study including patients diagnosed with axSpA fulfilling the criteria of the Assessment of SpondyloArthritis international Society (ASAS) 2009.

Clinical parameters, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath anklyosing spondylitis disease activity index (BASDAI) and Bath anklyosing spondylitis functional index (BASFI) were compared between groups of female and male axSpA.

Results: Two hundred axSpA patients were included with 31% of female (n=62) and a mean age of 43.3 ± 11.2 years. The mean age at onset of symptoms was 31.8 ± 8.9 years for women and 25.3 ± 9.1 years for men (p <0.0001). The mean age at diagnosis was 36.4 ± 9.7 years for women and 31.7 ± 10.4 years for men (p = 0.003). AxSpA with juvenile onset was noted in 1.7% of women and 12.1% of men (p = 0.02). Male axSpA were significantly more smokers (48.6% vs 5.4%; p <0.001). The mean duration of morning stiffness was 11.3 ± 9.2 minutes for women versus 21.6 ± 19.3 minutes for men (p = 0.005).

The mean ESR was 42.4 ± 29.8 mm for women and 28.3 ± 23.4 mm for men (p = 0.001). Radiographic sacroilitis was present in 69.3% of women versus 84.7% of men (p = 0.01). The use of anti-TNF alpha was less frequent in women (29% vs 48.5%; p = 0.01).

Our study did not found a statistically significant difference in peripheral manifestations, extraarticular manifestations, CRP, BASDAI and BASFI between the two groups.

Conclusion: Female axSpA seems to have a better prognosis than male with older age in disease onset, less inflammation, less radiographic sacroilitis and less use of biological treatments.
