Background: We present the first report of high-titer autoantibodies in NLRP3-associated autoimmune inflammatory disease (NLRP3-AID). Because systemic autoimmune inflammatory disease (SAID) is characterised by the lack of autoinflammatory T-cells or autoantibodies, we made a systematic review on the theme of autoantibodies in NLRP3-AID to clarify this phenomenon.

Objectives: We present the first report of high-titer autoantibodies NLRP3-AID, and discuss autoantibody in classical SAID.

Methods: We collected the clinical data of the patient with NLRP3-AID who had high-titer autoantibodies, and made a systematic review about autoantibody in SAID.

Results: A 38-year-old Chinese Han patient was definitely diagnosed as NLRP3-AID because of cold-triggered urticaria-like rash and fever, arthralgia, binoaral sensorineural deafness, chronic meningitis, high inflammatory marker, and de novo NLRP3 T348M variant. Figure 1 shows pedigree of the patient. Meanwhile, she had positive antineuclear antibody (ANA) with a nucleolar pattern of 1:160, positive anti-β2GPI antibody 54.86 AU/ml (normal range < 20 AU/ml), anti-thyroglobulin antibody 1244 mg/l (normal range < 30 mg/l), anti-mitochondrial antibody, and anti-nuclear antibodies. ANA with a nucleolar pattern was positive in 13 articles reported autoantibodies in Familial Mediterranean fever (FMF), and there was no autoantibody reported in hyperimmunoglobulinemia D syndrome (HIDS), TNF receptor–associated periodic syndrome (TRAPS) and NLRP3-AID. The prevalence of ANA, anti-β2GPI, RA and anti-CCP in patients with FMF was similar to healthy controls.

Conclusion: Patients with NLRP3-AID can have high-titer ANA and APLs by accident. If patients with high-titer autoantibodies have characteristic manifestations of SAIDs instead of typical features of autoimmune diseases, we should make the final diagnosis through detailed investigation and genetic testing.

A DESCRIPTIVE STUDY RELATED TO THE ADHERENCE BEFORE AND AFTER ENROLLING IN A MULTIDISCIPLINARY EDUCATIONAL PROGRAM

D. Buitrago-Garcia1, F. Rodriguez2, G. Sánchez3, P. Santos-Moreno3.
1Fundación Universitaria de Ciencias de la Salud, Epidemiology, Bogota, Colombia; 2Biomab - Center for Rheumatoid Arthritis, Patient Education Program, Bogota, Colombia; 3Biomab - Center for Rheumatoid Arthritis, Rheumatology, Bogota, Colombia

Background: Rheumatoid arthritis (RA) is an inflammatory, chronic disease. It leads to deformity and destruction of joints through the erosion of cartilage and bone. Patients with RA report to suffer symptoms in hands, joints, swelling, loss of motion, pain, and muscle weakness among others. (1) Centers of excellence in RA have proposed a multidisciplinary model of care with an initial diagnosis, treatment prescription and follow-up with a rheumatologist, periodic consultations with a physiatrist, psychologist, physiotherapist, occupational therapy, nutrition and a patient focused program(2). With this model of care, the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. However, if the patient does not adhere to the model becomes ineffective.

Objectives: The aim of this is to report the attendance to a multidisciplinary model of care for patients with RA that attend to a specialized center in Colombia before and after enrolling in a educational program.

Methods: We performed a descriptive study. Patients enrolled our educational program in July 2020. In our institution patients are followed-up under T2T standards and a multidisciplinary approach, as part of our model of care they have periodic consultations with a rheumatologist, physiatrist, psychologist, physiotherapist, occupational therapy, nutrition and a patient focused program(2). With this model of care, the patient is seen as a whole, and the expectation is to achieve the best results in the management of RA. However, if the patient does not adhere to the model becomes ineffective.

Results: We included 229 patients; mean age was 59 years ± 10; 93% were female. At the beginning of our program, mean DAS28 was 2.57 ± 1.19, from all patients 65% were at remission, 11% at low disease activity 19% at moderate disease activity and, 5% at severe disease activity. Regarding adherence to our model, the medical specialty with the highest attendance was rheumatology (30%) followed by, physical therapy (16%) physiatrist consultation (15%) and occupational therapy (11%); the specialty with the lowest attendance was nutrition (8%). After six months of attendance to the educational program, we found an increasing number of patients in remission 67%, low disease activity 15%, moderate disease activity 18%, we did not have patients with severe DA28. Regarding the medical specialties, we found a 3% rise in the attendance to the nutrition consultation and psychology consultation. We did not find statistical association between disease activity and adherence to the model.

Conclusion: These results are a clear example of how an educational program is capable of increasing awareness and improving the clinical outcomes and adherence to a multidisciplinary model for approaching RA. As other studies have shown(3), patient education interventions improve adherence to medication and to attendance to health care specialists.

Background: Primary care physicians (PCP) are usually the first contact of people with inflammatory rheumatic diseases, and find the early symptoms of Rheumatoid Arthritis (RA) difficult to distinguish from those of other rheumatic diseases. A time-delay in the reference to Rheumatology is a health issue in several countries. The clinical aspects that general practitioner took into account in hand arthralgia patients are important to make the reference. In particular the Squeeze Test (ST) - which is simple to perform and rapidly done, ST is useful for identifying progression to RA in patients with undifferentiated arthritis. The ST has been described as not reliable because is clinician-dependent.

Objectives: To identify the required force that needs to be applied in order to obtain a positive Automated Squeeze Test (AST) in a cohort of patients with hand arthralgia.

Methods: Ninety-seven patients were recruited in Family Medicine Consultation and in Rheumatology Consultation of the Hospital Universitario “Dr. José Eleuterio González” in Monterrey, Nuevo León, México. Eligible patients were adults (aged≥18 years) with hand arthralgia (that wasn’t caused by trauma) as their hand arthralgia. The diagnoses were Osteoarthritis (OA) (16.3%), RA (5.1%), Undifferentiated arthritis (1.2%), Psoriatic arthritis (1.2%) and Fibromyalgia (2%). Force measures used for compression.

Normal forces already predetermined in the interface of the software for identifying progression to RA in patients with undifferentiated arthritis. The ST was 51.14 years (SD 14.66). Ninety-six (97.9%) patients were right handed.

The diagnoses were OA (16.3%), RA (5.1%), Undifferentiated arthritis (1.2%), Psoriatic arthritis (1.2%) and Fibromyalgia (2%).

Results: In this cohort of 98 patients, 79 (80.6%) were women. The mean age was 51.14 years (SD 14.66). Ninety-six (97.9%) patients were right handed. The diagnoses were OA (16.3%), RA (5.1%), Undifferentiated arthritis (1.2%), Psoriatic arthritis (1.2%) and Fibromyalgia (2%). Force measures according to diagnoses are reported in Table 1.

OA: Osteoarthritis; RA: Rheumatoid Arthritis; UA: Undifferentiated Arthritis; PsA: Psoriatic Arthritis; FM: Fibromyalgia; SD: Standard Deviation

Conclusion: In the cases of RA and OA, the means of force to obtain a positive AST was lower than in the rest of the diagnoses.

Objectives: To determine the association between vitamin D deficiency and the degree of activity of the disease (inflammatory activity) in a cohort of patients with spondyloarthritis.

Methods: Case-control type analytical observational study. We propose a retrospective review of the database of patients with spondyloarthritis (according ASAS2010 criteria) who were treated in the outpatient clinics of the Rheumatology Service of the General University Hospital of Ciudad Real during June 2018 to June 2019. Patients with the data will be selected. necessary for the analysis of the variables under study. The numerical variables of normal distribution evaluated will be described using measures of frequency and measures of central tendency / dispersion as appropriate. To assess the association between vitamin D levels and activity index, the odds ratio (OR) is calculated, with a 95% confidence level and the T-student for related samples.

Results: The final results of the study are presented. 115 patients were analyzed, of which 64 were men and 51 women, with an average age of 45.97 years (+/- 13.41 DE). 47% were ankylosing spondylitis, 21% psoriatic arthropathy, 16% undifferentiated spondyloarthropathy, 7% spondyloarthropathy associated with inflammatory bowel disease and 9% were spondyloarthropathy associated with inflammatory bowel disease. The average of the activity was a BASDAI of 4.57 (+/- 2.36 SD) and measured by DAPSA was 12.61 (+/- 6.76 SD). 63 and 14 patients had activity measured by BASDAI and DAPSA, respectively. 49.56% patients presented an elevation of acute phase reactants. Vitamin D levels were 23.81 (+/- 10.5 SD). 77.4% presented figures of vitamin D deficiency or insufficiency. When performing the association analysis, the vitamin D deficiency presented an OR 10 (95% CI: 3.66-27.29, p=<0.0001) with the degree of activity measured with BASDAI and DAPSA and against the elevation of CRP it was 3.63 (95% CI 1.43-9.25, p = 0.0092) and against the elevation of ESR it was 2.76 (95% CI 1.09-7, 0, p = 0.0438). Regarding the comparative analysis of means between vitamin D deficiency/insufficiency and BASDAI/DAPSA it was +3.29 (95% CI: 1.34-8.09, p=0.0084).

Conclusions: Patients with spondyloarthritis, as in other autoimmune diseases, vitamin D deficiency is associated with increased inflammatory activity (BASDAI, DAPSA, CRP and ESR), measured in different time periods. Therefore, an optimization of vitamin D levels can imply an improvement in the patient’s clinical situation, measured by both BASDAI and DAPSA, as well as by CRP and ESR. In addition, it is necessary to monitor bone mineral density due to the risk of fracture in these patients for their multietiology (corticosteroid treatments, biological FAMEs, inflammatory activity).

Objectives: To establish the degree of concordance in the diagnosis of ILTB and interferon-gamma release assay in the screening of latent tuberculosis infection in patients who are going to initiate a TNF inhibitor.

Methods: The drugs that inhibit tumor necrosis factor (anti-TNF) alpha can reactivate a latent tuberculosis infection (LTBI) so requiring a rigorous screening before its onset. The tuberculin test (PT) has a high false negative rate in patients with immunemediated rheumatic diseases (IMID) and false positive in patients vaccinated with Bacillus Calmette Guérin (BCG). The neu methods of interferon gamma release (IGRA) seem to solve this problem, but its use is not standardized.

Objectives: Establish the degree of concordance in the diagnosis of LTBI between PT and IGRA in patients who are going to star an anti-TNF drug, in general, and in different situation like taking corticosteroids, being treated with disease modifying drugs, have been vaccinated with BCG or have risk factor for ILTB.

Background: The diagnosis of LTBI is a group of chronic inflammatory diseases with involvement of the axial skeleton (mainly), and also of peripheral joints. Patients with spondyloarthropathy have a significant prevalence of vitamin D levels below normal and that would correlate with the degree of activity of the disease.
