Background: Real-world data are missing for Ustekinumab (UST) and secukinumab (SEK) in psoriatic arthritis (PsA).

Objectives: To evaluate the characteristics of the patients (pts) with PsA treated by UST or SEK and to assess real world persistence of UST and SEK in PsA.

Methods: This is a retrospective, multicenter study of pts with PsA (CASPAR criteria or diagnosis confirmed by a rheumatologist) initiating UST or SEK with a follow-up ≥ 6 months from January 2011 to April 2019. The comparison of persistence between UST and SEK was analysed using a Cox model with an inverse probability of treatment weighting propensity score including 11 confounding factors. Subgroup analyses (age>65 years, gender, Body Mass Index (BMI), Charlson score>2, psoriasis, CRP>5mg/L, number (nb) of prior biotherapies, proportion of pts on maximum dose of UST or SEK, combination with methotrexate (MTX), enthesitic and axial forms of PsA) were also performed to test the heterogeneity of UST and SEK persistence. Finally, 2 sensitivity analyses were performed, first excluding the pts treated before the marketing authorization of SEK, and then excluding the pts that underwent a molecule switch. Causes of discontinuation were also collected.

Results: 406 pts were included: 245 with UST and 161 with SEK. At baseline before propensity score-matching, the UST group has a higher BMI (28.9 \pm $6.4 \text{ kg/m}^2 \text{ vs. } 27.4 \pm 6.0 \text{ kg/m}^2)$, more peripheral forms (98% vs. 90.8%), a higher nb of active smokers (27.1% vs. 19.9%), a higher frequency of psoriasis (96.3% vs. 83.2%), less MTX users (38.9% vs. 44.2%), a higher nb of pts with CRP >5mg/L (54.3% vs. 47%), a higher nb of pts naïve to biotherapies (22% vs. 13%) and a higher nb of pts with recommended dosing (97.3% vs 50.9%). The median persistence was 9.4 months and 14.7 months for UST and SEK, respectively. The persistence rate was lower in the UST group compared to the SEK group (40.9% vs. 59.1% % at 1 year; 26.4% vs. 38.0% at 2 years; weighted HR=1.42; 95% CI 1.07 to 1.92; p=0.015) (Fig 1). In subgroup analysis, combination with MTX was associated with a higher persistence rate in the patients with SEK compared to those receiving UST: 43.6% vs. 23.2% (HR=2.20; 95% CI 1.30 to 3.51; p=0.001), whereas no difference was observed in SEK and UST monotherapy: 33.8% vs 28.4%, respectively (HR=1.06; 95% CI 0.74 to 1.53; p=0.75) (Fig 2). A similar difference was found in the sensitivity analyses, with however a difference at the limit of significance for the analysis excluding pts with a molecule switch (adjusted HR=1.35; IC95% 0.96 to 1.92; p=0.085). The causes of discontinuation were due to inefficacy in 85% of cases and an adverse event in 12% of cases (19% in the SEK group and 9% in the UST group).

Conclusion: In this first real-world study comparing UST and SEK persistence in PsA, the persistence of SEK was longer than that of UST. Subgroup analysis revealed this difference of persistence was restricted to patients treated in combination with MTX.

770 Friday, 05 June 2020 Scientific Abstracts

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with comorbidities like obesity, metabolic syndrome, and cardiovascular disease. Adipose tissue leads to a pro-inflammatory status in obese subjects. For this reason, central obesity may determine a worsening in both disability index or quality of life in PsA patients treated with biologic agents.

Objectives: Our study aimed to evaluate the relationship between central obesity and disability index or the impact of the disease on quality of life in a real-world sample of PsA patients.

Methods: A cross-sectional study was conducted. Patients with PsA were enrolled at the PsA clinic at the ARNAS Civico in Palermo (Italy) from March 2018 to December 2019. Clinical, pharmacological, anthropometric, laboratoristic variables, and patient-reported outcomes, including the Health Assessment Questionnaire (HAQ) and Psoriatic Arthritis Impact of Disease (PsAID) were evaluated. STATA 14.1 was used to perform statistical analysis. Results: A total of 143 outpatients aged 55.6 (47.7-63.7) affected by PsA. according to CASPAR criteria, were consecutively evaluated. The average years of illness were 10.8 (9.5-12.1). Patients were treated with biological therapy (81.3%), DMARDS (41.6%), small molecules (9.9%), or their combinations, Both sexes were equally represented. 71.9% of enrolled patients had central obesity (64.9% men and 78.1% women) with an average waist circumference of 104.2 (101.8 - 106.6) for women and 103.6 (100.0 -107.2) for men. Average HAQ was 1.05 (0.92 - 1.19), and data analysis showed 50.3% of patients with normal-mild functional disability, 30.1% moderate to severe disability, and 19.6% severe to very severe disability [Fig 1]. 51,7% of the sample had a high impact of the disease on life, according to the PsAID questionnaire [Fig 2]. A strong association was observed between functional disability measured by HAQ >2 and central obesity [OR (95% CI) 16.94 (2.22 - 129.48); p < 0.006]. Moreover, data analysis showed an association between high impact of disease on life (PsAID >4) and central obesity [OR (95% CI) 3.33 (1.56 - 7.13); p<0,002].

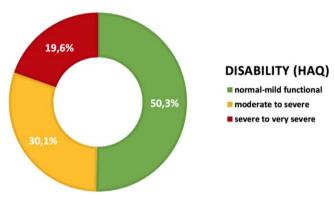

Fig 1. Functional disability on PsA patients

IMPACT OF DISEASE ON LIFE (PSAID)

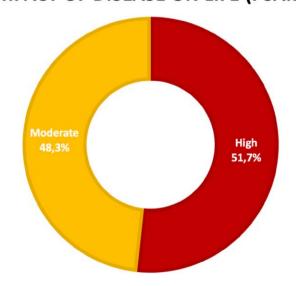

Fig 2. Impact of disease on PsA patients quality of life

Conclusion: Our study demonstrated a high association between functional disability studied subjectively using the HAQ, the impact of the disease on patients' quality of life using PsAID, and central obesity in Sicilian outpatients affected by PsA. Data suggest that therapeutic goals should not be focused on treatment but also on waist circumference reduction in order to reduce inflammation and improve patients' functional ability and quality of life.

FACTORS ASSOCIATED WITH PERIPHERAL EROSIVE RADIOGRAPHIC DISEASE IN A CONSECUTIVE SERIES OF 794 PSA PATIENTS

M. G. Catanoso¹, P. Macchioni¹, <u>A. Marchesoni</u>², S. D'angelo³, R. Ramonda⁴, A. Cauli⁵, F. Perrotta^{6,7}, R. Bortolotti⁸, M. Lofrano³, L. Rotunno², M. G. Lorenzin⁴, G. Valesini^{6,9}, G. Mathieu⁵, G. Paolazzi⁸, C. Salvarani¹. ⁷*ASMN IRCCS*, *Reggio Emilia, Italy*; ²*Rheumatology Unit, Orthopedic Institute G. Pini, Milano, Italy*; ³*Rheumatology Department of Lucania, San Carlo Hospital of Potenza, Potenza, Italy*; ⁴*Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova, Italy*; ⁵*University of Cagliari, Cagliari, Italy*; ⁶*University of Rome, Rome, Italy*; ⁷*Rheumatology Unit, Sapienza University, Department of Internal Medicine and Medical Specialties, Rome, Italy*; ⁸*Rheumatology Unit, Sapienza University, Department of Internal Medicine and Medical Specialties, Rome, Italy*

Background: Few studies have examined the correlation between clinical demographic and laboratory parameters with peripherical radiological erosive disease in PsA pts.

Objectives: To examine the association between clinical, demographical and laboratory data and the presence of radiographic erosions (RE) in the peripheral joints of psoriatic arthritis (PsA) pts.

Methods: A cross-sectional study was conducted in consecutive patients with PsA afferring 7 rheumatological italian tertiary care centers. Demographical, clinical, laboratory and imaging data were collected according to a standardized protocol. A patient was considered as affected by erosive disease (ED) if at least one joint presented radiographic erosions at hand and/or feet rx examination. Patients with ED at early rx examination (before 5 y from disease diagnosis) were considered as early ED (EED) pts and pts without ED at 6 y or more rx examination from disease diagnosis were considered as not EED (NEED). The association between the presence of joint erosions and demographical, clinical and laboratory data was assessed using logistic regression analysis. The results were expressed in terms odds ratios (OR), and 95% confidence intervals (CI).

Results: Rx hand and feet examination were available for analysis in 492/794 (39.9 % females, mean age 53.3 \pm 13.2 y, mean PsA duration 16.9 \pm 16.8 y, ED 171 pts). 48 pts had EED and 133 pts had NEED. At univariate analyses factors significantly associated with EED (p < 0.20) were PsA duration (OR=0.979,95%Cl 0.953-1.006, p = 0.119), diagnostic delay (OR=1.077, 95%Cl 1.018-1.138, p = 0.009), history of peripheral enthesitis (OR=2.308,95%Cl 0.904-5.888, p= 0.080), hypertrigliceridemia (OR=2.756,95%Cl 0.997-7.618, p = 0.0.051), hypercholesterolemia (OR=1.687, 95%Cl 0.777-3.661, p = 0.186), hyperuricemia (OR=0.450, 95%Cl 0.174-1.166, p = 0.10), use of biological agents (OR=1.712, 95%Cl 0.873-3.355, p=0.118). Factors significantly associated with EED at multivariate regression analyses were diagnostic delay (OR = 1.11, 95% Cl: 1.01, 1.22), history of enthesitis (OR = 3.15, 95% Cl: 1.23, 8.22), use of therapy with biological agents (OR = 3.60, 95% Cl: 1.31, 9.85) with protective effect of hyperuricemia (OR = 0.25, 95% Cl: 0.07, 0.90).

Conclusion: The presence of EED in a group of consecutive PsA patients is correlated to diagnostic delay and history of enthesitis. Longitudinal study may confirm these associations.
