counts (α-SMA staining) and of 23 serum inflammatory cytokines/chemokines (Mouse-Cytokine-23-plex, Bio-Rad Laboratories).

Results: 17-DMAG decreased dermal thickening by 53±3% (p<0.001) (nintedanib by 46±2%, p<0.001), collagen content by 40±4% (p<0.001) (nintedanib by 45±4%, p<0.001), myofibroblast counts by 42±9% (p<0.001) (nintedanib by 44±7%, p<0.001), and levels of IL-1α, IL-6, IL-12(p40), CXCL1, MCP-1, MIP-1β, RANTES (in all: p<0.05) compared to vehicle-treated mice injected with bleomycin for 6w. Moreover, 17-DMAG also induced reduction of pre-established fibrosis to below the levels of vehicle-treated mice injected with bleomycin for 3m and NaCl for 3w (dermal thickness by 14±3%, collagen content by 20±5%, myofibroblast counts by 13±9%; whereas in nintedanib by 10±3%, 21±4%, 17±7%, respectively, in all: p<0.05), and levels of IL-12(p40), CXCL1, MCP-1, MIP-1β, RANTES (in all: p<0.05). No significant weight loss, decrease in activity or changes in fur texture were observed upon 17-DMAG treatment.

Conclusion: This is the first study on effects of Hsp90 inhibitor 17-DMAG in the treatment of established dermal fibrosis. We demonstrate that 17-DMAG therapy potentially prevents the progression and induces regression of established bleomycin-induced dermal fibrosis, in an extent that is comparable to nintedanib in this study (which was recently FDA approved for slowing the rate of decline in lung function in adults with SSCc-ILD). 17-DMAG was well tolerated without obvious clinical signs of toxicity. These data suggest that 17-DMAG could be a novel potential target in the treatment of SSC dermal fibrosis.

OP0136 THE INFLUENCE OF LONG-TERM EXERCISE AND IN VITRO EXERCISE-MIMICKING STIMULATION ON THE PRODUCTION OF MYOKINES AND CYTOKINES IN MYOTUBES OF PATIENTS WITH CHRONIC INFLAMMATORY MYOPATHIES

M. Vokurová1, L. Vernerová1, M. Špirtovič2, H. Štokarová3, S. Oreska3, M. Klei1, J. Kukopec2, B. Kukočová1, M. Tomčík5, J. Vencovsky2,3-Institute of Rheumatology, Prague, Czech Republic; Institute of Rheumatology and Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic; Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic; Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia (Slovak Republic); Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences and Institute of Pathophysiology, Faculty of Medicine, Comenius University, Bratislava, Slovakia (Slovak Republic)

Background: It has been demonstrated several times that endurance exercise has beneficial effects on the condition of patients with idiopathic inflammatory myopathies (IM). Muscle contraction during exercise is a major stimulus for the release of myokines that are supposed to take part in the beneficial adaption to exercise.

Objectives: The aim of this study was to find out how a six-month physiotherapy and in vitro exercise-mimicking treatment affect myokine and cytokine production in myotubes of IM patients.

Methods: Seven patients with chronic IM took part in a six-month physiotherapy (stretching and strengthening), which significantly improved their muscle strength and endurance. IM patients (n=7) before and after the six months exercise and their respective healthy counterpart controls (HC, n=9) underwent a muscle wasuctus lateralis biopsy. Isolated skeletal muscle cells were grown, differentiated into myotubes, which were treated with a pharmacological cocktail (palmitate, forskolin and Ionomycin (PFI)) mimicking exercise-stimulated contractions in vitro. Myokine and cytokine concentrations produced by myotubes to the culture medium were analyzed with ELISA and the multiplex immunoassay, respectively. RT-PCR was used for the evaluation of myokine gene expression in the cultured myotubes.

Results: Compared to myotubes of healthy controls, myotubes of IM patient released more myostatin and activin A into the medium. The myostatin gene was expressed significantly more in myotubes of patients than in healthy controls' cells (p<0.05). After a six-month rehabilitation program, activin A secretion was four-fold reduced in myotubes of patients with IM, while myostatin release and gene expression remained unchanged. In myotubes of IM patients, less follistatin and more follistatin like 3 were detected in the culture medium compared to HC myotubes. Myotubes derived from IM patients after six months of rehabilitation secreted twice as much follistatin and half the amount of follistatin like 3 into the medium than myotubes derived from IM patients prior to rehabilitation (p<0.05). There was no difference in secretion of interleukin (IL) 6, IL-17, tumor necrosis factor (TNF) and vascular endothelial growth factor (VEGF) between myotubes of IM patients and myotubes of HC. However, six-month exercise significantly (p<0.05) reduced release of IL-6, TNF and VEGF in myotubes of IM patients. Contrary to our expectation, stimulation of PFI had no effect on the release of myostatin, activin A, follistatin and follistatin like 3, or the expression of their genes. PFI treatment significantly (p<0.05) increased IL-6 secretion in myotubes from HC and IM patients prior to six months of rehabilitation. On the other hand, it was observed that myotubes of HC and IM patients exposed to the PFI cocktail secreted significantly less inflammatory cytokines (IL-17, TNF-α and VEGF) into the medium compared to unstimulated myotubes (p<0.05).

Conclusion: In conclusion, long-term exercise influenced the production of myokines and decreased release of inflammatory cytokines in myotubes of IM patients. In vitro exercise-mimicking treatment increased the secretion of IL-6 and decreased the release of inflammatory cytokines as IL-17, TNF-α and VEGF in myotubes of patients with IM and healthy individuals.

Background: The analysis of annotated transcripts from genome-wide expression studies data is of paramount importance to understand the molecular phenomena underlying the occurrence of complex diseases, such as systemic sclerosis (SSc).

Objectives: To perform whole-blood transcriptome and pathway analysis on whole-blood (WB) RNA collected in two cohorts of European SSc patients. Via a discovery and validation strategy we aimed at characterizing the molecular pathways that differentiate SSc from controls and that are reproducible in geographically diverse populations.

Methods: WB samples from 252 controls and 162 SSc patients were collected in RNA stabilizers. Patients were divided into a discovery (n=79; Southern Europe) and validation cohort (n=83; Central-Western Europe). RNA sequencing was performed by an Illumina assay. Functional annotations of Reactome pathways were performed with the FAIME algorithm. In parallel, a immunophenotyping analysis on 28 circulating cell populations was assessed. We then tested the presence of differentially expressed genes and tested the association between absolute cell counts and RNA transcripts/FAIME scores in regression models. Results significant in both populations were considered as replicated.

Results: A total of 15224 genes and 1277 related functional pathways were available for analysis. Among these, 99 genes and 225 pathways were significant in both sets. The heatmap in figure shows the relative expression of Reactome pathways differentiated SSc from controls and that are reproducing in geographically diverse populations.

subtypes is jointly associated with RNA transcripts or FAIME scores with strong differences in relation to the geographical origin of samples; neutrophils emerged as the major determinant of gene expression in SSc-whole-blood samples.

**Conclusion:** We discovered a set of differentially expressed genes and pathways that could be validated in two independent sets of SSC patients highlighting a number of deregulated molecular processes that have relevance for the pathogenesis of autoimmunity and SSC.

**Background:** Idiopathic inflammatory myopathies (IIM, myositis) are a heterogeneous group of autoimmune muscle disorders characterized by skeletal muscle weakness and damage, inflammation and extramuscular manifestations. Recent findings suggest that immunological as well as nonimmunological processes, such as endoplasmic reticulum stress, hypoxia, mitochondrial and metabolic dysfunction are involved in the pathogenesis of IIMs [1]. Clusterin (CLU) has been reported to be involved in the cytoplasm of regenerating myofibers.

Our results show an up-regulation of clusterin in circulation and skeletal muscle of IIM patients that associates with disease activity and inflammation, and its specific expression in regenerating myofibers. Based on our data and the known cytoprotective function of CLU we suggest an attempt of the organism to limit further muscle damage induced by myositis disease mechanisms.

**Background:** Sjögren’s Syndrome (SS) and Systemic Lupus Erythematosus (SLE) are distinct chronic, complex autoimmune diseases with shared characteristics such as autoantibodies, heightened interferons, and polyarthritis. SS and SLE genome-wide association studies (GWAS) report strong associations with the DDX6-CXCR5 risk interval. DDX6 suppresses interferon stimulated gene expression and CXCR5 regulates T cell functions implicated in autoimmunity.

**Objectives:** To identify functional variants that impact regulation in the DDX6-CXCR5 risk interval.

**Methods:** Fine-mapping was done using ImmunoChip data from 3785 SLE, 1916 SS cases and 6893 population controls of European ancestry that were imputed and tested for SNP-trait association. Bayesian statistics assigned posterior probabilities to SNPs and defined a credible set of risk variants. Bioinformatic analyses further prioritized variants with predicted functionality. Electrophoretic mobility shift assays (EMSA)s and luciferase expression were used to validate predicted SNPs in EBV transformed B (EBV B) cells.

**Results:** While some differences were observed, the overall SS and SLE association signals were similar. SNP-SS rs736016 near CXCR5 and SNP-SLE rs76409436 near DDX6 were the most significant but did not show evidence of functionality. Bayesian statistics defined credible sets of variants in strong D’ in common between both SS and SLE. Bioinformatics analyses (Haploreg, RegulomeDB, ENCODE data, etc) further refined the credible set and identified 5 common SNPs with strong evidence of functionality in immune cell types: rs4938572, rs4906443, rs57494551, rs7117261 and rs4938573. EMSAs showed a significant increase in the recruitment of transcription factors to the risk allele of rs57494551 (p = 0.0001), rs7117261 (p = 0.0001) and rs4938573 (p = 0.0003), but not the others, using nuclear lysates from EBV B cells. Luciferase vectors with a minimal promoter or no promoter were used to test for enhancer or promoter activity, respectively. To this end, the rs57494551 risk allele exhibited a significant increase in enhancer activity (p = 0.0001). In contrast, the rs7117261 risk allele decreased enhancer activity.
