ABSTRACT

Background and aim Striving for harmonisation of specialty training and excellence of care in rheumatology, the European League Against Rheumatism (EULAR) established a task force to develop points to consider (PtCs) for the assessment of competences during rheumatology specialty training.

Methods A systematic literature review on the performance of methods for the assessment of competences in rheumatology specialty training was conducted. This was followed by focus groups in five selected countries to gather information on assessment practices and priorities. Combining the collected evidence with expert opinion, the PtCs were formulated by the multidisciplinary task force, including rheumatologists, medical educationalists, and people with rheumatic and musculoskeletal diseases. The level of agreement (LoA) for each PtC was anonymously voted online.

Results Four overarching principles and 10 PtCs were formulated. The overarching principles highlighted the importance of assessments being closely linked to the rheumatology training programme and protecting sufficient time and resources to ensure effective implementation. In the PtCs, two were related to overall assessment strategy (PtCs 1 and 5); three focused on formative assessment and portfolio (PtCs 2–4); three focused on the assessment of knowledge, skills or professionalism (PtCs 6–8); one focused on trainees at risk of failure (PtC 9); and one focused on training the trainers (PtC 10). The LoA (0–10) ranged from 8.75 to 9.9.

Conclusion These EULAR PtCs provide European guidance on assessment methods throughout rheumatology training programmes. These can be used to benchmark current practices and to develop future strategies, thereby fostering continuous improvement in rheumatology learning and, ultimately, in patient care.

INTRODUCTION

Rheumatology specialty training is the educational process required for a physician to formally become a specialist in rheumatology. It is defined by an officially approved training programme which aims to bring physicians to an agreed standard of proficiency regarding the management of people with rheumatic and musculoskeletal diseases (RMDs). The definition of the aims, structure and contents of each country’s rheumatology training programme is under the exclusive domain of national authorities. However, the harmonisation of specialist training in Europe is deemed essential to ensure equity of access to high standards of care for all people with RMDs and to support the movement of rheumatology specialists across countries.

For decades, educationalists have highlighted the relationship between learning and assessment. Indeed, learning is often driven by assessment. Assessment during training has a powerful impact on motivating learners on their path towards assessment for certification purposes. Regular and repeated testing can increase the retention of knowledge and the skill performance in undergraduate medical students. Even though evidence is scarce, the same paradigm is thought to apply to other types of assessment within higher education, such as specialty medical training.

The aim of this task force was to develop European League Against Rheumatism (EULAR) points to consider (PtCs) for the assessment of competences during rheumatology specialty training with the broader goals of enhancing learning during rheumatology specialty training, contributing to the harmonisation of training outcomes across Europe and improving the care provided to people with RMDs.

METHODS

After approval by the EULAR Executive Committee, the convenor (FS) and the methodologists (CH and SR) led a multidisciplinary task force guided by the 2014 updated EULAR standardised operating procedures. The task force consisted of 23 members, including rheumatologists with an interest in medical education (two of them also representing the Emerging Eular Network), a methodologist, a medical educationalist, and two people with RMDs, from 12 different countries. Two face-to-face meetings of the task force were held in November 2018 and October 2019. Two fellows (AA and AN), guided by the methodologists, performed a systematic literature review (SLR), retrieving individual studies on methods of assessment in rheumatology specialty training and SLRs of studies from other
Four overarching principles and 10 PtCs were formulated (table 2). Overall, the evidence underpinning these PtCs in the rheumatology setting is scarce, so the emphasis was placed on general expertise and consensus.

### Overarching principles
Rheumatology training should generate rheumatologists capable of and committed to delivering the best care to people with RMDs. During rheumatology training, the physician should acquire the knowledge, skills and professional behaviours necessary to ensure delivery of optimal care to people with all types of RMDs throughout their careers.

### Assessment of competences is vital to guide learning and to guarantee quality of care
In the past decades, there has been a move towards ‘assessment for learning’, in which the assessment environment encourages trainees to feel responsible for driving and appraising their own learning.

### Assessment is an integral part of training and must be guided by and aligned with a clear set of educational objectives established by the curriculum
The task force agreed on the need for assessments to be embedded into a structured strategy conveyed by the overall training programme. The curriculum provides the framework of learning objectives, each corresponding to adequate methods of teaching, learning and assessment. National curricula are available in most countries. Additionally, the UEMS Rheumatology Section and Board provides a European curriculum.

### Effective assessment requires protected time and resources
One of the key barriers to adequate assessment, identified by trainees and trainers alike throughout Europe, is the lack of protected time for this purpose. In order to improve the clinical learning environment, it is essential that educational supervisors, programme directors and national authorities recognise this need and identify and provide the necessary resources.
Formative assessment with constructive feedback should be regularly performed and with a greater frequency than summative assessment

Assessments can be performed with a formative or a summative aim. Summative assessment assigns grades to trainee performance at designated points in the curriculum, allowing comparison with established standards or between trainees, and a pass/fail decision. For example, an examination at the end of medical training, on which the decision to qualify for medical practice hinges, is a summative assessment. On the other hand, formative assessment is designed as an ongoing part of the instructional process to support and enhance learning and reflection. Formative assessment aims to stimulate the trainee to identify areas for improvement and to provide a plan to that purpose. Frequent, high-quality discussions about current performance, together with expert and customised suggestions for improvement, are associated with more effective learning and higher satisfaction in trainees.¹⁵

Feedback should stimulate reflection by the trainee on how to achieve the standards of competence and professional behaviour.

Feedback is a core component of effective assessment, informing trainees of their progress (or lack of), observed learning needs (and available resources to facilitate learning) and providing motivation to undertake appropriate learning activities.¹⁶ Feedback has the potential to change physicians' behaviour in different environments,¹⁷ including clinical performance and professional conduct. Feedback should prompt self-reflection and management of the weaker aspects of performance. In the focus groups, both trainees and trainers identified feedback as a priority.¹⁶

Trainees should maintain an updated portfolio, including feedback and evidence of self-reflection, to be used as part of the assessment process.

Portfolios are instruments used to collect and assess evidence of a trainee’s experience and progression in tasks and competences.¹⁸ They provide a key connection between learning at individual and organisational levels. The implementation of portfolios throughout Europe varies, and there is no consensus on their aims, design and content. The task force felt that portfolios should extend beyond a ‘logbook’ list of patients managed, procedures performed, courses attended or research performed. Rather, they should be an integral part of the continuous formative process and self-learning; as such, they should include examples of assessors' feedback and trainees’ self-reflection. In order to promote honesty and self-critique, reflections included in the portfolio should be kept private and should not be misused or misconstrued in legal contexts. Use of electronic portfolios and, even better, integration within e-learning platforms increase their utility and address one of the key complaints of trainees,¹⁹ the excessive time spent in their compilation. The EULAR portfolio task force has developed a portfolio structure which can be considered for uptake in different countries.¹⁹

Different methods of assessments should be carried out throughout training, as no single method of assessment can provide a complete overview of trainee competences.

During training, rheumatologists acquire a wide variety of competences ranging from the ability to independently manage people with different forms of RMDs to the performance of specific skills (eg, aspirating a knee joint) or the acquisition of professional attitudes (eg, commitment to lifelong learning). No

### Points to consider

Assessment of competences should be a structured and continuous process, regularly carried out throughout the training period

As assessments should not be performed at a unique time point (eg, final examination); rather, they should be spaced out throughout the training, allowing the trainee to identify areas for improvement before a final summative assessment. Providing a specific recommendation on minimum or optimal assessment frequency was discussed in depth by the task force; however, it was thought that this needed to be flexible enough to be applied in different national contexts. Frequency should be enough to provide adequate feedback and to guide learning throughout the training programme. Some types of assessment, such as the identification of unprofessional behaviours with appropriate feedback, should take place continuously.

**Notes:**
- LoA: level of agreement; LoE: level of evidence; RCT: randomised controlled trial.
- Numbers in the column ‘LoA’ indicate the mean (SD) of the LoA and the percentage of trainee members with an LoA of at least 8 (0–10). LoA: based on the Oxford Centre for Evidence-Based Medicine classification, with ‘level 1’ corresponding to meta-analysis or RCTs; ‘level 2’ corresponding to lesser quality RCTs or prospective comparative studies; ‘level 3’ corresponding to case–control studies or retrospective studies; ‘level 4’ corresponding to case series without the use of comparison or control groups; and ‘level 5’ corresponding to case reports or expert opinion.¹¹ LoA, level of agreement; LoE, level of evidence; RCT, randomised controlled trial.

67

single method of assessment can properly evaluate all competences. For example, written exams are unable to assess how a trainee works within a multidisciplinary team or whether they can perform a joint injection. In fact, the correlation between scores from assessment tools evaluating different competences is very weak.\textsuperscript{20–24} On the other hand, different assessment methods can be used to assess a single competence, providing complementary information. For instance, the ability to aspirate a joint can be assessed with a mannequin (simulation) or on a real person with an RMD (eg, workplace-based via direct observation of procedural skills (DOPS)). In the second instance, assessment of a trainee’s skill in patient communication or respect for patient autonomy can be included. When implementing a training programme and designing a local assessment strategy, thought must be given as to how each competence is assessed.

Multiple-choice case-based questions should be the preferred form of knowledge assessment

Each competence is composed of the integration of specific knowledge, skills and professional behaviours.\textsuperscript{25} When assessing knowledge, we are therefore not assessing overall competence, but one of the core pillars that support it. Emphasis was placed on the fact that multiple choice questions (MCQs) should be based on a clinical scenario (case-based), allowing the assessment of complex clinical reasoning rather than the mere memorisation of specific facts. Oral examinations, commonly known as vitrius, are not recommended as the inclusion of few examiners, the sampling of limited content and the use of a global judgement result in poor reliability.\textsuperscript{26}

Clinical skills should be assessed in the workplace (DOPS) or the mini-clinical examination exercise (mini-CEX) and/or in a simulated context (observational structured clinical examination (OSCEs))

Clinical skills and competences can be assessed in a simulated environment or directly in the workplace. In simulated environments, the recommended assessment tool is the OSCE. An OSCE consists of multiple, time-limited stations where trainees perform specific tasks, under structured assessment. At each station, trainees are marked against standardised scoring checklists by trained assessors. In this manner, an OSCE can assess many competences. Typical competences assessed in this manner include performing a site-specific clinical examination, discussing treatment options or skills such as the identification of crystals in a synovial fluid sample.\textsuperscript{20,21} Patient experts can be trained to role-play a patient with a given disease. In workplace assessments, a trainer observes the trainee interacting with a patient around a clinical task (mini-CEX) or a procedure (DOPS). The trainer uses a structured form to assess and provide feedback to the trainee. Encounters can take place in a variety of settings (inpatient, outpatient, emergency room) and contexts (initial or follow-up visit). The mini-CEX can be used to assess competences such as taking a focused history or performing a physical examination, while the DOPS is tailored for procedures such as joint aspiration, crystal identification or joint ultrasonography. Overall, each patient encounter takes 15–30min followed by 5–10min of feedback. It is expected that trainees are assessed several times throughout the year of training, with different trainers and in different clinical situations or with different focuses, so that different competences are assessed.\textsuperscript{5} A similar case may be especially dedicated to assess clinical examination or management planning, for example. The EULAR portfolio task force is developing forms for both the mini-CEX and the DOPS.\textsuperscript{19}

Competences related to professionalism should be formally assessed using multisource feedback (MSF)/360° method

Professionalism is key to a good clinical practice and should be part of training and assessment. However, the assessment of professionalism is hampered by varying definitions and the difficulty in transforming the elements of professionalism into aspects that can be taught and measured.\textsuperscript{27} It is beyond the scope of these PtCs to establish which aspects of professionalism should be assessed; these could include areas such as ethical practice, effective interaction with patients and relatives, working effectively with other health professionals, health authorities and other stakeholders, reliability and commitment to continuous improvement.\textsuperscript{28} The MSF, also known as the 360° evaluation, allows the systematic collection of data on a trainee’s performance, acquired anonymously from a variety of coworkers. Typically, 10–20 assessors comment on a specified range of that person’s functioning. The assessors may include trainers, physicians, trainees, nurses, medical students, health professionals, patients and administrative personnel. MSF is especially useful in assessing actual behaviours in the workplace which are difficult to measure, or which can be concealed under formal assessment conditions. The results from the MSF should be discussed with the trainee in order to promote reflection.

The training programme should incorporate a predefined process to identify and support trainees at risk of failure

The identification of trainees who are at risk of failure within training programmes is a challenge.\textsuperscript{29} Some trainers feel unprepared and/or unwilling to report a trainee’s underperformance. Barriers include lack of documentation, lack of knowledge of what to document, anticipation of an appeal process and lack of remediation options.\textsuperscript{30} Assessor development programmes, a strong assessment system with clear standards to be achieved at different training levels and a support system that offers guidance to the failing trainee are deemed essential.\textsuperscript{31}

Trainers should receive regular training in assessment methods and strategies, particularly in providing constructive feedback

The existence, depth and scope of development programmes in assessment methods vary widely among countries\textsuperscript{10} and can even be training centre-specific. Accepted training and assessment methods evolve with time as new evidence accrues. Continuous professional development in assessment methods and strategies should be encouraged by relevant stakeholders. Of special importance is training in providing constructive feedback,\textsuperscript{32} a far more complex competence than it may seem. There is a recognised gap between the feedback given and what is perceived by the trainee. Feedback is effective when it leads to an improvement in the performance of the trainee. Both the skills of the person selecting and providing the feedback and the willingness and ability of the recipient to engage with it can modulate its effectiveness.

DISCUSSION

These are the first EULAR-endorsed PtCs for the assessment of competences in rheumatology specialty training. Their aim is to serve as a benchmark and an inspiration to involved stakeholders. In total, 41 EULAR countries provide rheumatology specialty training. Each country has its own training structure, curriculum and assessment strategy, resulting in a wide heterogeneity.\textsuperscript{2} Some countries provide a comprehensive list of assessments to be undertaken, while some provide national, summative final examinations, and others provide broad statements. Overall,
the specific implementation remains largely dependent on each centre’s culture and attitude. These PtCs in no way attempt to undermine local regulations. Rather, they seek to provide recommendations of good practice, which can help stakeholders analyse their own assessment strategy and inspire positive change, where appropriate.

Many practising physicians are involved in assessing the competences of trainees. However, some are not as comfortable using educational assessment tools as they are managing patients with RMDs. Assessment tools can measure knowledge or demonstrate competence in a simulated or in a ‘real-life’ setting. Written examinations with MCQs can assess pure knowledge, but they are best employed in assessing its application to clinical problems; for this purpose, context-specific questions, based on a clinical scenario should be used. OSCEs can evaluate a trainee’s skills and competences in a simulated environment. OSCEs can be used for both common or rarer diseases, highlighting the need for systematic assessment that might provide clues for the differential diagnosis, while rare diseases might be difficult to evaluate in workplace-based assessments. However, in order to evaluate what a trainee actually does, assessment needs to take place within the workplace by direct observation of a trainee’s performance in a ‘real-life’ setting. Implementing a structure and effective assessment strategy within a busy clinic is a challenge, highlighting one of the barriers to workplace assessment. Tools such as the mini-CEX or the DOPS facilitate the standardisation of the assessment and feedback of clinical encounters and procedures. Professionalism is key to becoming an effective physician but is one of the most difficult aspects to define and measure. While some aspects of professionalism can be assessed in a simulated context (eg, efficient patient communication in an OSCE), most should be explored in the workplace. The major barrier for effective implementation of this multimodal assessment strategy is lack of time and resources (eg, trained trainers). Support from training centres, institutions and national authorities is key.

Even though specific evidence from rheumatology studies supporting these PtCs was scarce, the LoA with the PtC was very good. Published evidence identified in the SLR was limited to the evaluation of some aspects of validity or reliability of a few assessment tools (OSCE, mini-CEX and DOPS). Indirect evidence, stemming from other medical specialties, provides additional support, but its applicability is varied, given the different contexts. As per EULAR standard operation procedures, the Oxford Levels of Evidence have been applied. In medical education, quantitative evidence is scarce; specifically, evidence assessing the impact of different tools or strategies is lacking. Research allowing rheumatologists to implement best practices supported by consistent evidence would be welcome and is the basis of the proposed research agenda (box 1). While we await this, the high level of consensus that these recommendations provided is reassuring as to its cross-national validity.

In conclusion, these EULAR PtCs provide European guidance on assessment tools and strategies to be used throughout rheumatology training programmes. Given the relationship between learning and assessment, the harmonisation of assessment strategies could impact rheumatology training, encouraging stakeholders to strive for excellence and thereby optimise the future care delivered to people with RMDs.
