Background: Cognitive impairment (CI) in systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) patients have been poorly described and recognized.

Objectives: to describe the rates and spectrum of CI in primary (PAPS) and secondary to systemic lupus erythematosus (SLE) (SAPS) APS patients.

Methods: 113 patients (70 with APS (37 – PAPS, 33 – SAPS) and 43 - SLE without APS), 89 (78.8%) – women, were consecutively enrolled in the study. The mean (M±SD) age was 37.9±11.9 years. SLE activity was measured by SLEDAI scale. Mental disorders (MD) were diagnosed by psychiatrist in accordance with ICI-10 in semi-structured interview. CI were diagnosed with psychology and neuropsychology methods.

Results: CI of varying severity were found in 105 (92.9%) patients: 62.9% - mild, 23.8% - moderate and 13.3% - severe. Severe and moderate CI were more associated with APS (46.6% in PAPS and 39.5% in SAPS vs 18.6% in SLE, p=0.004 and p=0.04, accordingly). CI were predominantly organic in all patients, but vascular dementia was detected only among patients with APS (10.8% of PAPS and 3.03% of SAPS patients). There was no association of CI with clinical manifestations and activity of APS. In 60 patients (74.3%) CI also were specifically bound to MD. Current MD were detected in 100 (88.5%) patients: schizotypal disorder was found in 10 (8.8%) patients and was associated with PAPS (13.5% vs. 9.9% in SAPS and 4.65% in SLE); anxiety-depressive spectrum disorders (ADDs) - in 95 (84.1%) (chronic and recurrent depression prevailed 37 (32.7%) and 42 (37.2%) resp.); the structure of MDs in accordance with ICI-10 differed slightly between groups, but no statistically significant differences were obtained.

Conclusion: cognitive impairment, mainly of an organic type, are characteristic of most patients with SLE and APS. The significant associations of cognitive impairment with clinical manifestations and activity of SLE were not identified, but patients with cognitive impairments were more likely to have anxiety and depressive disorders, strokes, livedo reticularis and lupus anticoagulant positivity.

months after vaccination. During the observation period, none of the patients had an exacerbation of the disease, reliably associated with the vaccination. There was no recurrence of thrombosis, both in patients receiving anticoagulant therapy and without it. No new autoimmune phenomena, both clinical and laboratory, were identified. The dynamics of the production of anti-streptococcal antibodies during the year was followed in 16 patients. One year after vaccination, 31% of patients showed a significant (more than 2-fold compared to the initial) increase in the concentration of antibodies to polysaccharides of the cell wall of S. pneumoniae (“responders”), 69% of patients were “non-responders” to the vaccine. At the same time, all 5 patients with PAPS were “non-responders,” and 45.5% “responders” with sAPS.

Conclusion: Preliminary results show that patients with APS tolerate PPV-23 vaccination well. In the next post-vaccination period, exacerbations of the disease, thrombosis were not recorded. Attention is drawn to the large number of “non-responders” in PAPS, however, to obtain statistically reliable results, it is necessary to continue the study and recruit more patients.

AB0311 INCREASED LEVELS OF SERUM WISTERIA FLORIBUNDAGGLUTININPOSITIVE MAC-2 BINDING PROTEIN IN RHEUMATIC DISEASES INCLUDING SLE

T. Yoshikawa1, K. Azuma1, T. Furukawa1, M. Tamura1, T. Hashimoto1, M. Morimoto1, N. Azuma1, K. Matsui1. 1Hyogo College of Medicine College Hospital, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya-City, Japan

Background: Mac-2 binding protein is a cell-adhesive glycoprotein of the extracellular matrix secreted as a ligand of galectin-3 (Mac-2). Recently, a Wisteria floribunda agglutinin positive-M2BP (M2BP) assay developed using a lectin-antibody sandwich immunocassay has shown promise as a new fibrotic marker in liver fibrosis and interstitial lung disease (ILD) to detect unique fibrosis-related glycoalteration.

Objectives: The aim of this study is to evaluate the utility of serum Mac-2 binding protein glycosylation isomer (M2BPGi) levels in patients with rheumatic diseases (RD).

Methods: We retrospectively measured serum M2BPGi levels in 68 patients with RD and 16 healthy controls (HC). There were no patients of cirrhosis and active hepatitis. Serum levels of M2BPGi were measured using HISCL M2BP glycosylation isomer Assay Kit. We examined the relationship between serum M2BPGi levels and clinical parameters in patients with RD.

Results: In patients with RD, the median age was 62.0 years and 79.4% of them were female. Serum M2BPGi levels were significantly higher in patients with RD than in HC (median 0.98 cutoff index [COI], 0.32 COI, respectively; P < 0.00001). Patients with SLE tended to have higher serum M2BPGi levels than other rheumatic diseases. In patients with RD, a significant correlation was not found between serum M2BP levels and inflammation markers such as CRP or ferritin. However, serum M2BPGi levels were significantly correlated with B cell activation markers such as immunoglobulin free light chain and IgG (r = 0.588, 0.504) and T cell activation marker such as sIL-2R (r = 0.408).

Conclusion: Most of the rheumatic diseases in this study were considered to be type I interferonopathy diseases such as rheumatoid arthritis, Sjogren’s syndrome, inflammatory myositis, scleroderma and SLE. Serum M2BPGi was reported to have a significant correlation with SLE disease activity [SS Ahn et al. Lupus. 2018; 27: 771], and also to have a significant correlation with Gakectin-9, a novel biomarker for IFN signature [Lucas L van den Hoogen et al. Ann Rheum Dis. 2018; 77: 1810]. So, it was suggested that serum M2BP/Gi may be a novel biomarker that indirectly indicates how much IFN is activated in rheumatic diseases.

AB0312 INCREASED PREVALENCE OF OBSTRUCTIVE SLEEP APNEA IN INDIVIDUALS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Meidan1,2, D. Paran3,2, R. Taumaran2,4, V. Furev2,3, T. Eviatar2,3, D. Levartovsky2,3, A. Polacheck2,3, J. Wollman2,3, H. Padova2,3, M. Zisaelp2,3, M. Anok2,3, E. Seymour2,5, O. Elkayam2,5, O. Eliaouf2,3, Tel Aviv Sourasky Medical Center, Internal Ward B, Tel Aviv, Israel; Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv, Israel; Tel Aviv Sourasky Medical Center, Sleep Medicine Center, Tel Aviv, Israel; Tel Aviv Sourasky Medical Center, Neurology, Tel Aviv, Israel

Background: Sleep disturbances are common in individuals with rheumatological diseases in general and systemic lupus erythematosus (SLE) in particular. Studies suggest that obstructive sleep apnea (OSA) might correlate with SLE disease activity and the presence of additional symptoms such as pain, fatigue, affective symptoms and steroid use6. Sleep disturbances symptomatology such as fatigue and increased pain overlap with constitutional inflammatory symptoms of SLE and may mimic or mask disease related relapse.4,5 Therein lies the importance of diagnosing and treating such disorders in SLE.

Objectives: To determine whether patients with SLE have increased prevalence of OSA as assessed by the apnea hypopnea index (AHI) and to explore possible contributors to OSA including SLE disease activity and accrued damage, medications, secondary fibromyalgia and depression.

Methods: 42 consecutive patients with SLE (38 women, 4 men) and 20 healthy, sex, body mass index (BMI) and age matched controls (15 women, 5 men) were consecutively recruited and underwent an ambulatory sleep study using the WatchPAT device. All participants completed questionnaires including Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Functional Assessment of Chronic Illness Therapy (FACIT), Widespread Pain Index (WPI), Symptom Severity Scale (SSS) and Beck Depression Inventory. SLE disease activity and damage were assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborating Clinics (SLICC) damage index.

Results: The mean AHI was 9.19 ± 6.79 in the SLE group and 3.95 ± 3.47 in the control group (p=0.004). Moderate-severe OSA (AHI>15) was significantly more common in patients with SLE (23.6% vs. 0%, p=0.04). Patients with SLE had lower sleep efficiency (83.38 ± 6.15 vs. 87.22 ± 4.24, p=0.03), increased sleep arousals (772 ± 5.66 vs. 5.13 ± 2.29, p=0.01), higher PSQI and FACIT scores SLE (8.14 ± 3.47 vs. 5.10 ± 2.64, p=0.001, 16.89 ± 11.19 vs. 729 ± 5.93, p= 0.0008 respectively) and had more fibromyalgia as assessed by WPI and SSS
