OBJECTIVES: To explore the incidence of esophageal dilation on high-resolution CT in SSc patients and factors that might influence its prevalence.

METHODS: Ninety-two SSc patients (72 females, 20 males) with a mean age of 59.9 ± 11.4 years were included in this retrospective study. Esophageal dilation was defined as a maximum transverse diameter of the esophagus ≥ 2 cm. Data on demographics, clinical features, laboratory tests, and medical history were collected. Logistic regression analysis was conducted to identify factors associated with esophageal dilation.

RESULTS: The prevalence of esophageal dilation was 50% (46/92). Factors found to be significantly associated with esophageal dilation included age (OR = 1.03, 95% CI: 1.01-1.06, p = 0.009) and female gender (OR = 2.4, 95% CI: 1.1-5.2, p = 0.03). No significant associations were found with disease duration, skin thickness, arthritis, or pulmonary hypertension.

CONCLUSION: Esophageal dilation is a common finding in SSc patients, with age and female gender being significant risk factors. Further studies are needed to elucidate the pathophysiological mechanisms underlying esophageal dilation in SSc.

Considering the bone status, patients with Hcy showed a significantly lower TBS (p=0.03); the average values of BMD on the lumbar spine (p=0.79) and femoral neck (p=0.13) were found lower compared to, but without any statistical significance. Furthermore, no significant differences were observed in bone turnover markers according to Hcy levels.

Conclusion: The study demonstrates a relationship between higher levels of Hcy and lower TBS values within SSC patients, particularly in those with more severe microvascular damage al NVC (“Late” SSC pattern). Therefore it is concluded that higher serum levels of Hcy associate to both bone microarchitectural and microvascular damage in SSC.

CAPILLAROSCOPIC PATTERNS IN PATIENTS WITH SYSTEMIC SCLEROSIS-POLYMYOSITIS/DERMATOMYOSITIS (SSc-PDM/DM) OVERLAP SYNDROME
O. Desinoyva1, M. Starovoytova1, L. P. Ananyeva1, VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation

Background: Impaired microcirculation is one of the leading factors in local and general pathogenesis of SSC. Widespread nail-fold video-capillaroscopy (NFC) stands as the most informative and at the same time simple method used for evaluation of capillary circulation.

Objectives: To identify characteristic and specific for SSc- PM/DM capillaro- scopic features.

Methods: Both hand II – V fingers of 68 pts with SSc-P/DM were subjected to widefield NFC, evaluated using a binocular 20x magnification Olympus microscope and analyzed in view of specific skin lesions discriminating diffuse and limited SSC forms.

Results: SSC-specific dilatations of capillary loops were the most common for SSc-P/DM and were found in all pts; 50% of them had signs of active scleroderma pattern, such as capillary loss or ‘avascular areas’ (50%) and herniations (51.5%), associated with generalized microvascular spasm in early disease and capillary sclerosis in advanced disease. The morphological capillary abnormalities such as varying degrees of capillary loops tortuosity/vascular inhomogeneity were present in 63% of examined nailfolds, branching bushy behavior of capillary loops and mega-capillaries predominated; architectural disorientation/disarrangement of capillary loops with formation of subcutaneous plexus was seen in more than 50% of them. Capillaroscopic changes consistent with active scleroderma pattern were present in 54 % and were associated with lab signs of inflammatory muscle syndrome and immunological disor- ders: giant capillaries (p<0.02), disorientation of capillary loops (p<0.02) and ramified/bushy capillaries (p=0.04) were significantly more frequent in patients with severe muscle involvement, increased CPK, ANF-positivity and herniations (p<0.03).

Conclusion: Thus, widefield NFC revealed a “mixed” nature of capillaroscopic changes, combining features specific for SSC (capillary dilation, avascular areas, herniations) and for PM/DM (bushy and giant capillaries, disorientation of capillary loops of the nailfold with formation of subcutaneous plexuses.)

CLINICAL AND IMMUNOLOGICAL FEATURES OF THE SYSTEMIC SCLEROSIS-OVERLAP SYNDROMES
O. Desinoyva1, M. Starovoytova1, L. P. Ananyeva1, O. Shayakhmetova1, O. Ovsyannikova1, VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation

Background: Systemic Sclerosis (SSc) overlap syndromes (SSc with polymyositis / dermatomyositis (PM/DM), rheumatoid arthritis (RA), etc.) still remain a group of very heterogeneous and not very well studied clinical variants of SSc that are characterized by certain clinical and immunological features.

Objectives: Identify clinical and immunological features of the SSc-overlap syndromes.

Methods: 80 pts with SSc-P/DM and 35 pts with SSc-RA undergoing standard clinical examination and laboratory immunological evaluation.

Results: ANA Hcp2 was positive in 98% of SSc-P/DM pts; a-Scl-70 was in 34%, a - PM-Scl and RF were in 20%, ACA (6%), a-RNP (9%), and a - Jo-1 (5%) were significantly less common. Correlation analysis showed significant prevalence of conduction abnormalities in pts with a-Scl-70 (p<0.03); PM-Scl was rarely asso- ciated with cardiac arrhythmia (p=0.02) and pericarditis (p<0.03), but there was an association between ACA and presence of digital ischemia (p>0.04). Three pts with limited skin had Scl-70 and PM-Scl antibodies, two of them manifested clinical features of DM. A-Jo-1 was found in 3 pts with a longstanding disease (14, 10 and 7 years), and one of these pts was also positive for a-Scl-70. All pts had limited skin and two had interstitial lung disease with P/F ratios of 79% and 74.8%.

ANA Hcp2 was positive in 96% of SSc-RA pts; a-Scl-70 – in 28%, and a-RNP - in 30%. RF-positivity was in 72% of pts, and Anti-CCP - in 27%. Simultaneous Anti- CCP and a-Scl-70 was found in one case, and Anti-CCP - a-RNP – in another, both were associated with low RF titters. All pts had early joint involvement which became prevailing in subsequent years, and onset of the disease between 30 and 40 years. There was a correlation between laboratory signs of inflammatory activity and immunological disorders: ESR and a-Scl-70 (p<0.03). Anti-CCP and a-Scl-70 co-positivity was a significantly less frequent phenomenon (p>0.04).

Conclusion: There was a remarkable 28% proportion of a-Scl-70 cases in SSc-RA with limited cutaneous which is usually characterized by ACA-positivity.

NAILOFDCAPILLAROSCOPIC AND CANDIDATE BIOMARKER LEVELS IN SYSTEMIC SCLEROSIS-ASSOCIATED PULMONARY HYPERTENSION: PROFILING OF NON-INVASIVE MARKERS, A COHORT STUDY
J. Lemmers1, C. H. M. Van den Ende1, R. Smeets1, B. Kersten1, A. Van Caam2, S. Van Leuven1, J. Van Haren-Willems1, A. Van Dijk1, M. Vonk1, 1Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; 2Radboud University Medical Center, Laboratory for Clinical Chemistry, Nijmegen, Netherlands; 3Radboud University Medical Center, Laboratory of Experimental Rheumatology, Nijmegen, Netherlands; 4Radboud University Medical Center, Pulmonology, Nijmegen, Netherlands; 5Radboud University Medical Center, Cardiology, Nijmegen, Netherlands

Background: Systemic sclerosis (SSc) is characterized by inflammation, vascu- lopathy and progressive fibrosis. Pulmonary Hypertension (PH) is one of the lead- ing causes of death in SSc (1). Currently, most patients with SSc are screened for the presence of PH, and focus lies on early detection and early treatment. Recent literature describes potential for both nailfoldcapillaroscopy (NFC) and several biomarkers to serve as non-invasive tools to identify SSc patients at risk for developing PH (2). Ideally this could contribute to further improvement of risk stratification in SSC and PH screening algorithms.

Objectives: To explore NFC characteristics and plasma levels of selected can- didate biomarkers in a cross-sectional cohort of SSc patients with and without different forms of PH.

Methods: From 02-2018 until 02-2019 we included 40 consecutive SSc patients with associated PH (30%) were female, 32 (80%) LCSSc, median age 72 years (IQR 69-77), median SSc duration 10.7 years (IQR 4.3-17.8), median PH duration 3.9 years (IQR 1.5-70.6) and 40 without PH (28) (70%) were female, 26 (65) had a LCSSc, median age 59 years (IQR 51-71), median SSc duration 6 years (IQR 3-15.6). In each group NCM characteristics (both quantitative and qualitative) and plasma levels of IL4, IL6, IL8, IL13, PDGFAA, PDGFBAB-B, 6Ckine, sTRAIL, MMP1, MMP7, sCAM1, sVCAM, CCL19/MP30, Endostatin, sVEGFR1, sVEGFR2, sVEGFR3, CXCL4, Endothelin1, GF1, GF2, VEGF-A, VEGF-C, and VEGF-D using Luminex kits, and vascular auto-antibodies AT1R and ETAR using ELISA (Celldiag GmbH, Luckenwalde, Germany) were determined. NCM characteristics were compared using t-tests, biomarker levels were compared by using Mann-Whit- ney U tests.

Results: We observed no differences in mean capillary density, number of abnormally shaped capillaries, number of fingers with density <3 capillaries/mm and in overall NCM pattern between patients with and without PH. Plasma levels showing significant differences between the two groups are presented in table 1.

Conclusion: We found significant differences in several of the selected biomark- ers in SSc patients with and without PH, but not in NCM characteristics between the groups. However, we did observe a tendency toward more morphologic abnormalities and an overall late pattern in the SSc-PH group. Future longitudinal research should explore the added value of these NCM parameters and biomark- ers in personalized risk stratification for the development of PH.
