characteristics of the disease (subtype of JIA, disease duration). The level of education, marital status as well as the profession were recorded.

Results: The study included 32 patients with a female predominance: sex ratio was 1.5. The mean age of the patients was 18.5 years old [18-64]. The mean age of onset of the disease was 6 years and 2 months [2-17]. The frequency of each JIA subset was as follows: polyarticular with rheumatoid factor (n=14), polyarticular without rheumatoid factor (n=9), systemic (n=2), enthesis-related arthritis (n=7), oligoarthritis (n=5). Four patients suffered from bilateral carpal tunnel disease. Polyarticular RF+ and RF- progressed into an authentic spondyloarthropathy (n=71.4) and 67.6% respectively. Among enthesiopathic subtypes, the extension of the disease to a polyarticular RF+ form (n=11) and to a seronegative rheumatoid arthritis (n=1) was noted. Systemic JIA forms remained in remission with an articular involvement. All the patients with ERA developed spondyloarthropathies. About forty–two percent of the patients were married, only half of them had children. Ten percent of patients stopped attending school because of disease flares and deformations. A university level was found in 16% of cases. Only Thirty patients had a profession. Of the patients, 74.4% had received disease-modifying anti-rheumatic drugs (DMARDs) and 36.3% of them were still taking a DMARD. Ten patients were on biologics. Severe disability was found in 20% of patients and concerned mainly the hip (52.7%), the wrist (28.5%) and the elbows (14.3%). Prosthetic joint replacement was found in 2% of cases with a revision of the latter in one patient.

Conclusion: Adults with JIA often have significant levels of disability, usually related to severe joint complications. There is a clear requirement for a better transition to adulthood and a socio-professional rehabilitation.

THE NAIL FOLD CAPILLAROSCOPIC FINDINGS OF ADOLESCENTS WITH ANOREXIA NERVOSA AND BULIMIA NERVOSA
M. Kacak-Cucecou1,1, M. Pehlivanturk-Kizilkan2, E. Sag3, S. Sener4, Z. Balik1, S. Akgu5, D. Dermann6, Y. Bilginer7, N. Kanbur8, S. Ozener9, Hacettepe University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey; 2Hacettepe University, Department of Pediatrics Division of Adolescent Medicine, Ankara, Turkey

Background: The nail fold video capillaroscopy (NVC) is usually performed on patients with microcirculation problems, such as Raynaud’s phenomenon. It is also used to distinguish between primary and secondary Raynaud’s Phenomenon and identify the scleroderma pattern.

Objectives: To describe the acute phase nail fold capillaroscopic findings of adolescents with anorexia nervosa (AN) and bulimia nervosa (BN) and to compare these findings with adolescents diagnosed with primary Raynaud’s phenomenon (RP).

Methods: We included 17 AN, 2 BN patients and 6 adolescents with primary RP as a control group. The nail fold video capillaroscopy (NVC) data of three study groups were compared. AN and BN patients were classified according to DSM-5. The participants in these two groups were assessed for the presence of Raynaud’s phenomenon/acrocyanosis and the weight loss history (amount and duration), daily calorie intake, vital signs, hydration status, amenorrhea presence and time, the presence and frequency of compensatory behaviors, and drug usage were recorded. Adolescents with primary RP were diagnosed according to ‘International consensus criteria for the diagnosis of RP’. The initial NVC was performed at the acute phase of AN and BN. For AN acute phase is defined as the period where the nutritional rehabilitation has not yet taken place. The NVC analysis was performed by a digital USB microscopy by an expert blinded to the participant’s clinical status and diagnosis. Eight fingers were evaluated for each patient and average of all fingers’ scores were used as quantitative measures.

Results: Among adolescents with AN, 14 of them had enlarged capillaries (capillary diameter 20-50 μm) and 6 of them had mild tortuosity (<50%) which were considered as minor capillaroscopic changes. 5 patients had at least one giant capillary (>50μm), 3 of them had microhemorrhages, 4 of them had capillary ramifications, and 1 of them had capillary disorganization which were considered as major capillaroscopic changes. Two adolescents had capillary loss (6 capillary/mm). The mean capillary diameter had 29.5 (μm) (n=12). Within the primary RP group, there were minor findings as five adolescents had mild capillary dilution (capillary diameter 20-50 μm), and 5 had mild tortuosity (<50%). However, none had scleroderma (early-acute-late phase) findings. Microangiopathy assessment scores revealed no difference between the AN patients with and without RP and primary RP patients (Table 1). A positive correlation was found between capillary ramification scores and initial daily calorie intake (r: -0.47; p=0.04).

Conclusion: Preliminary results of our study suggest that adolescents with AN are at risk for vasculopathy especially during the acute phase of the disease.

JUVENILE IDIOPATHIC ARTHRITIS AND SCHOOLING
H. Tantou1, K. Nassar1, S. Janani1, Faculty of Medicine and Pharmacy, Hassan II University, Ibn Rochd University Hospital Center, Rheumatology, Casablanca, Morocco

Background: Juvenile idiopathic arthritis (JIA) refers to all chronic inflammatory rheumatism in children without a recognized cause, onset before the age of 16. JIA is associated with significant short- and long-term disability, which influences the education and socio-professional integration of patients who suffers from it.

Objectives: Evaluate the impact of JIA on the education and professional integration of affected patients.

Methods: This is a retrospective, descriptive and cross-sectional study carried out in the rheumatology department. We included all patient followed in our JIA training.

The following information was collected from a questionnaire survey: Educational attainment, main problems experienced during studies, cause of dropping school, and professional data.

Results: Forty-two patients were included. The average age was 27.15 years old [18 - 61 years old]. Sex-Ratio (M / F) was 0.9. The forms of JIA experienced several problems during their studies: joint pain and stiffness (73.52%), absenteeism (50%), limitation in activities (26.47%), problem with memory (17.64%), problem with concentration (23.52%), limited attention (11.76%), and difficulty to stay awake (5.88%). Only 2.94% of patients experienced several problems during their studies: joint pain and stiffness (73.52%), absenteeism (50%), limitation in activities (26.47%), problem with memory (17.64%), problem with concentration (23.52%), limited attention (11.76%) and fatigue (5.88%). Only 2.94% of patients benefited from an individualized reception protocol apart from a sports exemption which represents 38.23%. 73.52% of patients received encouragement to continue their studies by those around them (parents, teachers and attending physicians).

Discontinuation of schooling was observed in 70.58% of patients with 8.82% of patients dropping school before the onset of JIA and 61.76% of patients related to severe joint complications. There is a clear requirement for a better education and socio-professional integration of patients who suffers from it. School studies were still ongoing in 23.52% of patients.

Regarding the professional side, unemployment affects 52.94% of these patients and workers represent 23.52%.

Conclusion: In our series, the level of education of JIA patients does not exceed secondary level in 80% of cases. The implementation of an individualized reception protocol is strongly recommended to facilitate the education of these patients and to fight against the main problems experienced. The professional integration of patients with JIA should also be adopted.
