

Supplemental Figure A. Peptides that were not selected to complete full external validation.

ELISA was performed on SSA- subjects (n=8) and control subjects (n=8) that were the same as the subjects used for the array. A-E: Peptides bound more by SSA- subjects than controls showed low binding (mean OD<0.05) or fewer than half of SSA- subjects bound more than the standard error of the mean of controls.

F-G: Peptides bound less by SSA- subjects had very low binding among controls; H-I: Internal validation results for peptides for which we started external validation but midpoint analysis showed no trend toward higher binding among SSA- subjects. Control had no known autoimmune disease; SSA- SJD met 2016 ACR/EULAR criteria for SJD but were anti-SSA antibody negative.
