Paradoxical gastrointestinal effects of interleukin-17 blockers

We read with great interest the review written by Fauny *et al*¹ which describes the relevance of interleukin-23/T-helper 17 (IL-23/Th17) pathway in inflammatory bowel disease (IBD). However, drugs targeting IL-17 have shown the opposite effect with worsening of the disease seen in patients with IBD leading to premature termination of various trials.^{2,3} Not only that, IL-17 inhibitors have also triggered new onset IBD in patients with spondyloarthritis. Consequently, the authors suggest a careful search for symptoms or family history of IBD as well as screening using faecal calprotectin levels in patients being planned for anti-IL-17 therapy. So far, the exact mechanism of this perplexing effect has not been elucidated and the authors have suggested that decreased intestinal barrier, predisposition to infection and subsequent inflammation may be responsible for worsening of IBD following anti-IL-17 therapy. We hereby describe other plausible pathways that can explain the same.

Th17 cells were first described in 2005⁴ by Langrish *et al* in a mice model of experimental autoimmune encephalitis. Since then, their role has been described in various autoimmune diseases including rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and IBD.⁵ Therapies targeting the same have been beneficial in patients with AS and PsA leading to their use as second-line therapies after TNF (tumour necrosis factor) inhibitors.⁶ However, trials using drugs targeting IL-17 have failed or at best been modestly effective in RA and uveitis,^{7,8} and have been detrimental in IBD.¹

An interesting concept that has recently evolved explains lack of efficacy of blocking IL-17 in a murine model of experimental autoimmune uveitis.⁹ In an elegant series of experiments, the authors propose an autocrine loop in which IL-17A by acting through NF- κ B, induces IL-24 production by Th17 cells. IL-24 then acts as a regulatory cytokine and represses IL-17F and granulocyte macrophage colony stimulating factor (GM-CSF) through SOCS1 and SOCS3. IL-24 is a member of IL-10 family of cytokines which signals through the IL-20 receptor.¹⁰ The receptors for IL-24 are mainly expressed on epithelial cells including the colonic mucosa. It is produced by activated immune cells including T and B cells, and has a suppressor effect on Th1 and Th17 cells.¹¹ In Th17 cells, IL-24 transcription occurs in late phase of activation suggesting that it may have a role in regulation of Th17 response. High levels of IL-24 have been demonstrated in the skin in psoriasis, synovial fluid in RA and intestinal mucosa in IBD; however, it seems to have an immune regulatory role.¹² The recent paper actually proves that induction of IL-24 in turn inhibits IL-17F and GM-CSF production.⁹

Further, IL-24 increases mucin production by increasing MUC gene expression supporting suppressive effects on mucosal inflammation in IBD.¹³ A dose-dependent action of IL-24 has been seen, with lower doses suppressing the Th1 cells and higher doses promoting Th1 and Th17 mediated inflammation.¹⁴ Thus, blocking IL-17A might interfere with this regulatory loop and lead to worsening of inflammation. This needs to be further evaluated in animal models of IBD as it may imply that dual IL-17A and F blockade with drugs (bimekizumab) could be effective in IBD.

Further, patients with IBD who had evidence of higher inflammatory load like elevated C-reactive protein and faecal calprotectin showed a poor response to secukinumab.² The same trial also demonstrated absence of the minor allele of TNF-like ligand 1A (TL 1A) to be strongly associated with lack of response. TL

1A, expressed by macrophages, along with IL-23, promotes interferon gamma and IL-17 production by T cells in the gut mucosa.¹⁵ In a dextran sodium sulphate mice model of IBD, overexpression of TL 1A, probably by reducing barrier proteins like occludin and claudin-1 through Th9 cells, increased gut permeability resulting in subsequent inflammation.¹⁶

Thus, though the exact reason for the paradox of IL-17 inhibition in IBD is not known, but interference in the gut mucosal barrier, a possible regulatory role of IL-17A via IL-24, excessive inflammation mediated by TL 1A and underlying genetic basis may explain this puzzle partly. Understanding this paradox can throw light on complex role of IL-17 in autoimmune diseases and chronic inflammation.
